Abstract

Quantum algorithms for simulating Hamiltonian dynamics have been extensively developed, but there has been much less work on quantum algorithms for simulating the dynamics of open quantum systems. We give the first efficient quantum algorithms for simulating Markovian quantum dynamics generated by Lindbladians that are not necessarily local. We introduce two approaches to simulating sparse Lindbladians. First, we show how to simulate Lindbladians that act within small invariant subspaces using a quantum algorithm to implement sparse Stinespring isometries. Second, we develop a method for simulating sparse Lindblad operators by concatenating a sequence of short-time evolutions. We also show limitations on Lindbladian simulation by proving a no-fast-forwarding theorem for simulating sparse Lindbladians in a black-box model.

1 Introduction

The original motivation for quantum computers came from the observation that such a device would be ideally suited to simulating quantum systems [20]. Over the past two decades, there has been substantial work on the development of quantum algorithms for simulating Hamiltonian dynamics. Lloyd [31] gave the first explicit quantum algorithm for efficiently simulating local Hamiltonians. Aharonov and Ta-Shma [1] introduced the more general notion of sparse Hamiltonians and showed that they can also be simulated efficiently. The complexity of sparse Hamiltonian simulation was subsequently improved using approaches based on product formulas [6, 12, 15], discrete-time quantum walks [7, 13], and methods for implementing linear combinations of unitaries [8–11, 16, 32].

Hamiltonian dynamics represent an idealized scenario in which the system is perfectly isolated. More generally, a quantum system coupled to an inaccessible environment can evolve nonunitarily. Such open quantum systems arise naturally in areas including quantum statistical mechanics and quantum optics, and in the description of realistic quantum information processors that are subject to noise. However, there has been relatively little work on quantum algorithms for simulating open quantum systems.

In this paper, we focus on quantum algorithms for simulating Markovian quantum dynamics, a well-studied special case that describes a situation in which a system is coupled to a large, memoryless environment. For an N -dimensional system with density matrix ρ , such dynamics can be described by a Lindblad equation [29] of the form

$$\frac{d\rho}{dt} = \mathcal{L}(\rho) = -i[H, \rho] + \sum_j (L_j \rho L_j^\dagger - \frac{1}{2}(L_j^\dagger L_j \rho + \rho L_j^\dagger L_j)), \quad (1)$$

where H is an $N \times N$ Hermitian matrix and the L_j are $N \times N$ matrices called *Lindblad operators*. The superoperator \mathcal{L} that generates the dynamics is called the *Lindbladian*. We say that a Lindbladian \mathcal{L} can be efficiently simulated if, for any $t, \epsilon > 0$, there exists a quantum operation \mathcal{E} consisting of $\text{poly}(n, t, 1/\epsilon)$ gates such that $\|\mathcal{E} - e^{\mathcal{L}t}\|_\diamond < \epsilon$, where $\|\cdot\|_\diamond$ is the diamond norm (see [Definition 4](#) below).

Of course, one possible approach to simulating open quantum systems is to explicitly simulate the environment [\[41, 43\]](#). However, this introduces considerable overhead, and it is challenging to analyze such an algorithm rigorously. To the best of our knowledge, the only case for which explicit, efficient algorithms have been presented is the setting of open quantum systems with local interactions (i.e., with Lindblad operators that act nontrivially on a constant number of qubits). Kliesch et al. [\[27\]](#) gave the first efficient algorithm for this case. That work has been extended to some non-Markovian open systems [\[38\]](#), and its performance has been improved [\[39\]](#) using higher-order product formulas [\[36, 37\]](#).

More generally, it may be useful to have efficient algorithms for simulating Lindbladians that are not necessarily local. Such a framework might be applied to develop quantum algorithms based on Markovian dynamics, just as sparse Hamiltonian simulation can be used to implement adiabatic optimization [\[1\]](#), quantum walk algorithms [\[14, 18\]](#), and the quantum linear systems algorithm [\[24\]](#). It might also be useful for simulating realistic systems that are not necessarily described by local Lindbladians, just as sparse Hamiltonian simulation has been useful in the context of quantum chemistry (see for example [\[3\]](#) and references therein). (We give a simple example of such a Lindbladian, a truncated version of a damped harmonic oscillator, in [Section 5.3](#).)

Just as in Hamiltonian simulation, a simple counting argument shows that Lindbladians must have some special structure to be efficiently simulated. In particular, it would be natural to develop an analog of sparse Hamiltonian simulation for Markovian dynamics. In this paper, we develop two approaches to simulating sparse Lindbladian dynamics.

First, we develop a simulation framework that we call the sparse Stinespring isometry framework. As in sparse Hamiltonian simulation, we divide the Lindbladian into a sum of terms, each of which generates evolution within a low-dimensional subspace. To simulate one such term, we implement it by a sparse Stinespring isometry, which we show how to implement efficiently in [Theorem 2](#). The quantum algorithm first implements the isometry using an ancilla system and then uncomputes this ancilla to obtain the correct isometry. While the first step is reasonably straightforward, the second is more technically challenging, requiring careful application of the orthogonality properties of the Stinespring isometry to uncompute the ancilla without disturbing the effect of the first step.

Second, we develop a method for simulating Lindbladians with sparse Lindblad operators ([Theorem 8](#)). We simulate such Lindbladians by concatenating a sequence of short-time evolutions, where the error in the implementation of each piece is quadratic in the evolution time. By generalizing efficient implementation of sparse unitaries [\[25\]](#), we implement these pieces by approximately implementing a sparse map that we show is close to the desired quantum operation.

We apply these two methods to simulate five classes of sparse Lindbladians, which we characterize in terms of a matrix that we call the *overcomplete GKS matrix*, denoted A . When the Lindbladian acts on an N -dimensional system, A is an $N^2 \times N^2$ matrix.

These simulations are summarized in [Table 1](#). We call the first class *identical-coordinate Lindbladians* because the nonzero entries of the overcomplete GKS matrices have two identical coordinates for the row, and similarly for the column. In particular, if all Lindblad operators of a Lindbladian are diagonal, then this Lindbladian is identical-coordinate. In the second class, *sparse-diagonal Lindbladians*, the overcomplete GKS matrix A is diagonal, and the diagonal of A is described by a d -sparse matrix. If the matrix A is diagonal but its diagonal is not described

class	nonzero entries	# nonzeros	rank	result
Identical-coordinate	$A_{(k,k),(l,l)}$	$\Theta(N^2)$	$\Theta(N)$	Theorem 4
Sparse-diagonal	$A_{(k,l),(k,l)}$	$\Theta(dN)$	$\Theta(dN)$	Theorem 5
Dense-diagonal	$A_{(k,l),(k,l)}$	N^2	N^2	Theorem 6
1-ket-sparse	$A_{(k,l),(k,l)}, A_{(k,l),(\nu(k),l)}$	$\Theta(N)$	$\Theta(N)$	Theorem 7
Sparse Lindblad operator	$A_{(\nu_i(k),k),(\nu_j(l),l)}$	$\Theta(N^2)$	$O(1)$	Theorem 8

Table 1: Summary of the main results of this paper. The second column describes the nonzero entries of the matrix A characterizing the overcomplete GKS form presented in (3). Here ν is a permutation that encodes the location of the nonzero entries. The third and fourth columns describe the number of nonzero entries and the rank of A , respectively, where N is the dimension of the Hilbert space and d is the sparsity.

by a sparse matrix, then it may be difficult to simulate in general. However, we define a class of *dense-diagonal Lindbladians* for which the entries of the diagonal can be partitioned into N sets of identical entries, such that with appropriate query access to partial sums of the entries, these Lindbladians can be simulated efficiently. The fourth class of efficiently simulatable Lindbladians, which we call *1-ket-sparse Lindbladians*, has nonzero off-diagonal entries, but the sparsity is special as the permutation is independent of the second coordinate of both rows and columns. In the fifth class of Lindbladians, the Lindblad operators are sparse.

More generally, our results show how to efficiently simulate any Lindbladian that can be expressed as a positive linear combination of (efficient unitary transformations of) Lindbladians from the five classes represented in [Table 1](#), together with local Lindbladians.

We describe two applications of our results. First, we show how to efficiently simulate a truncated damped quantum harmonic oscillator, which is not described by a local Lindbladian. Second, we give an efficient implementation of open quantum walks—a mutual generalization of classical Markov chains and quantum walks—on sparse graphs.

Finally, we also show a limitation on Lindbladian simulation by proving a no-fast-forwarding theorem for Markovian quantum dynamics ([Theorem 10](#)). For two natural black-box models of sparse Lindbladians, we show that the complexity of a simulation for time t is at least linear in t .

The remainder of this paper is organized as follows. In [Section 2](#), we define the overcomplete GKS form, invariantly d -sparse Lindbladians, and d -sparse Stinespring isometries, and establish an equivalence between the latter two notions. We also discuss product formulas for superoperators. Then, in [Section 3](#), we establish our sparse Stinespring isometry framework, which reduces the Lindbladian simulation problem to the task of finding the Gram vectors of a certain matrix and efficiently implementing a sparse Stinespring isometry defined in terms of these Gram vectors. In [Section 4](#), we apply this framework to efficiently simulate four classes of nonlocal Lindbladians. Then in [Section 5](#), we show how to simulate Lindbladians with sparse Lindblad operators. In [Section 6](#), we describe how to use our results to efficiently simulate open quantum walks. We then turn to limitations on simulation in [Section 7](#), where we prove a no-fast-forwarding theorem for Lindbladians. Finally, we conclude in [Section 8](#) and present some open problems about simulating open quantum systems.

2 Preliminaries

2.1 Overcomplete GKS form

Gorini, Kossakowski, and Sudarshan [21] gave an equivalent characterization of Markovian quantum dynamics that is a convenient alternative to the Lindblad equation (1). Given a basis $\{\sigma_i\}_{i=1}^{N^2-1}$ of traceless operators on $N \times N$ density matrices, \mathcal{L} is the generator of a Markovian open system evolution if and only if it can be written as

$$\mathcal{L}(\rho) = -i[H, \rho] + \sum_{i,j=1}^{N^2-1} A_{ij}([\sigma_i \rho, \sigma_j^\dagger] + [\sigma_i, \rho \sigma_j^\dagger]) \quad (2)$$

for some $N \times N$ Hermitian matrix H and some $(N^2 - 1) \times (N^2 - 1)$ positive semidefinite matrix A .

It is more convenient for our purposes to choose a basis of matrix elements in the computational basis. Although the resulting form is no longer unique, it provides a natural setting to describe sparse Lindbladians. The resulting *overcomplete GKS form* is as follows. Here and throughout this paper, let $[N] := \{0, 1, \dots, N-1\}$.

Theorem 1. \mathcal{L} is a Lindbladian if and only if there exists an $N^2 \times N^2$ positive semidefinite matrix A with entries $A_{(k,l),(k',l')}$ for $k, l, k', l' \in [N]$ such that

$$\mathcal{L}(\rho) = -i[H, \rho] + \sum_{k,l,k',l' \in [N]} A_{(k,l),(k',l')} (2\langle l|\rho|l'\rangle|k\rangle\langle k'| - \delta_{kk'}|l'\rangle\langle l|\rho - \delta_{kk'}\rho|l'\rangle\langle l|). \quad (3)$$

Proof. For each j in (1), write the Lindblad operator L_j in the computational basis in the form

$$L_j = \sum_{k,l \in [N]} a_{j;(k,l)} |k\rangle\langle l|. \quad (4)$$

Then

$$\begin{aligned} & \sum_j (L_j \rho L_j^\dagger - \frac{1}{2}(L_j^\dagger L_j \rho + \rho L_j^\dagger L_j)) \\ &= \frac{1}{2} \sum_j \sum_{k,l,k',l' \in [N]} a_{j;(k,l)} a_{j;(k',l')}^* (2\langle l|\rho|l'\rangle|k\rangle\langle k'| - \delta_{kk'}(|l'\rangle\langle l|\rho + \rho|l'\rangle\langle l|)). \end{aligned} \quad (5)$$

Define an $N^2 \times N^2$ matrix A with composite indices by

$$A_{(k,l),(k',l')} := \frac{1}{2} \sum_j a_{j;(k,l)} a_{j;(k',l')}^*. \quad (6)$$

Clearly, A must be positive semidefinite. On the other hand, if A is positive semidefinite, it can always be written in the above form using the spectral decomposition. \square

2.2 Sparse Stinespring isometries

We develop a framework for simulating sparse Lindbladians by implementing sparse Stinespring isometries. We begin by defining notions of sparsity for Lindbladians and quantum operations.

Definition 1. A linear map \mathcal{T} on density matrices is d -sparse if for any pair $(x, y) \in [N]^2$,

$$\mathcal{T}(|x\rangle\langle y|) \in \text{span}\{|x'\rangle\langle y'| : x' \in S_x, y' \in S_y\}, \quad (7)$$

where $S_x \subseteq [N]$ is the set of basis states to which $|x\rangle$ can transit and $\max_x |S_x| \leq d$. If for arbitrary $x \neq y$, either $S_x \cap S_y = \emptyset$ or $S_x = S_y$, then we say \mathcal{T} is invariantly d -sparse.

Invariantly sparse operations are especially simple since their evolution is confined to low-dimensional subspaces. In particular, observe that for any invariantly d -sparse Lindbladian \mathcal{L} and any time $t > 0$, $\mathcal{E} = e^{\mathcal{L}t}$ is an invariantly d -sparse quantum operation.

In our sparse Stinespring isometry framework, we focus on simulating invariantly d -sparse Lindbladians. It is helpful to have a similar notion of invariant sparsity for Stinespring isometries.

Definition 2. An isometry V is invariantly d -sparse if for any $x \in [N]$,

$$V|x\rangle = \sum_{i \in [r_x]} |\nu^i(x)\rangle |\phi_{x,i}\rangle \quad (8)$$

for some (not necessarily normalized) states $|\phi_{x,i}\rangle$, where ν is a permutation of order at most d and $r_x \leq d$ is the order of x .

The assumption that ν is a permutation of order at most d ensures that the quantum operation obtained by applying V and tracing out the ancilla is invariantly d -sparse. More precisely, we have $|S_x| = r_x$ for each x , and we may assign a cyclic order of all r_x elements in S_x according to the order of their indices. Thus ν can be viewed as a “neighbor function” where the first neighbor of x is $\nu(x)$, the second neighbor of x is $\nu^2(x)$ (which is also the first neighbor of $\nu(x)$), etc. Then we have $S_x = \{x, \nu(x), \dots, \nu^{r_x-1}(x)\}$, which contains all $r_x - 1$ neighbors of x together with itself.

Example 1. With $N = 7$, suppose $S_0 = S_1 = S_4 = S_5 = \{0, 1, 4, 5\}$ and $S_2 = S_3 = S_6 = \{2, 3, 6\}$. Then we can take the elements of S_0 (or S_1, S_4, S_5) in the order $0 \rightarrow 1 \rightarrow 4 \rightarrow 5 \rightarrow 0$ and of S_2 (or S_3, S_6) in the order $2 \rightarrow 3 \rightarrow 6 \rightarrow 2$. In other words, we can define the permutation ν to be $\nu(0) = 1, \nu(1) = 4, \nu(2) = 3, \nu(3) = 6, \nu(4) = 5, \nu(5) = 0, \nu(6) = 2$.

Our definitions of invariantly d -sparse quantum operations and invariantly d -sparse Stinespring isometries are equivalent in the following sense:

Proposition 1. A quantum operation \mathcal{E} is invariantly d -sparse if and only if there exists an invariantly d -sparse Stinespring isometry V such that

$$\mathcal{E}(\rho) = \text{Tr}_{\text{anc}}[V\rho V^\dagger] \quad (9)$$

for all density matrices ρ .

Proof. The “if” part is trivial since a d -sparse Stinespring isometry can only map $|x\rangle\langle y|$ into $\text{span}\{|x'\rangle\langle y'| : x' \in S_x, y' \in S_y\}$, where $S_x = \{x, \nu(x), \dots, \nu^{r_x-1}(x)\}$ for arbitrary x . Also, for arbitrary $x \neq y$, either $S_x \cap S_y = \emptyset$ or $S_x = S_y$.

It remains to prove the “only if” part. Assume that a quantum operation \mathcal{E} is d -sparse. Since for arbitrary $x \neq y$ either $S_x \cap S_y = \emptyset$ or $S_x = S_y$, we may define a permutation ν of order at most d for any input such that $S_x = \{x, \nu(x), \dots, \nu^{r_x-1}(x)\}$ for arbitrary x , where $r_x = |S_x| \leq d$ is the order of x . Without loss of generality, we may assume that $r_x = d$ for each x . Thus we may write

$$\mathcal{E}(|x\rangle\langle y|) = \sum_{i,j=0}^{d-1} a_{ij}^{xy} |\nu^i(x)\rangle\langle \nu^j(y)| \quad (10)$$

for all $x, y \in [N]$. Since \mathcal{E} is trace-preserving,

$$\text{Tr} [\mathcal{E}(|x\rangle\langle x|)] = 1 \quad \Rightarrow \quad \sum_{j=0}^{d-1} a_{jj}^{xx} = 1 \quad \forall x \in [N]; \quad (11)$$

$$\text{Tr} [\mathcal{E}(|x\rangle\langle \nu^i(x)|)] = 0 \quad \Rightarrow \quad \sum_{j=0}^{d-1} a_{i+j,j}^{x\nu^i(x)} = 0 \quad \forall x \in [N], i \in \{1, \dots, d-1\}. \quad (12)$$

By (10), the Choi matrix of \mathcal{E} , defined as $J(\mathcal{E}) := (\mathcal{E} \otimes \mathcal{I})(\sum_{x,y} |x\rangle\langle y| \otimes |x\rangle\langle y|)$, is

$$J(\mathcal{E}) = \sum_{x,y=0}^{N-1} \left(\sum_{i,j=0}^{d-1} a_{ij}^{xy} |\nu^i(x)\rangle\langle \nu^j(y)| \right) \otimes |x\rangle\langle y|. \quad (13)$$

The Choi matrix of any quantum operation is positive semidefinite. In other words, for any state $|\varphi\rangle = \sum_{k,l=0}^{N-1} c_{kl}|k\rangle|l\rangle$, we have $\langle \varphi | J(\mathcal{E}) | \varphi \rangle \geq 0$. By (13), this is equivalent to

$$\sum_{x,y=0}^{N-1} \sum_{i,j=0}^{d-1} c_{\nu^i(x),x} a_{ij}^{xy} c_{\nu^j(y),y} \geq 0. \quad (14)$$

Denote

$$M_{\mathcal{E}} := \sum_{x,y=0}^{N-1} \left(\sum_{i,j=0}^{d-1} a_{ij}^{xy} |i\rangle\langle j| \right) \otimes |x\rangle\langle y|, \quad |c\rangle := \sum_{z=0}^{N-1} \sum_{k=0}^{d-1} c_{\nu^k(z),z} |k\rangle|z\rangle, \quad (15)$$

where we call $M_{\mathcal{E}}$ the Gram matrix of \mathcal{E} (see Definition 3 below). Equation (14) is equivalent to

$$\langle c | M_{\mathcal{E}} | c \rangle \geq 0. \quad (16)$$

Since (14) holds for any $|\varphi\rangle \in \mathbb{C}^{N \times N}$, equation (16) also holds for any $|c\rangle \in \mathbb{C}^{dN}$. In other words, $M_{\mathcal{E}}$ is positive semidefinite.

Since every positive semidefinite matrix is a Gram matrix, $M_{\mathcal{E}}$ is a Gram matrix. In other words, there exist vectors $\{|\phi_{x,i}\rangle\}_{i=0}^{d-1}$ for each $x \in [N]$ such that for all $x, y \in [N]$ and $i, j \in [N]$,

$$\langle \phi_{y,j} | \phi_{x,i} \rangle = a_{ij}^{xy}. \quad (17)$$

For each x , define $V|x\rangle := \sum_{i=0}^{d-1} |\nu^i(x)\rangle |\phi_{x,i}\rangle$ as in (8). Then by (11), (12), and (17), V is a d -sparse Stinespring isometry:

$$\|V|x\rangle\|^2 = \sum_{j=0}^{d-1} \|\phi_{x,j}\|^2 = \sum_{j=0}^{d-1} a_{jj}^{xx} = 1 \quad \forall x \in [N]; \quad (18)$$

$$\langle \nu^i(x) | V^\dagger V | x \rangle = \sum_{j=0}^{d-1} \langle \phi_{\nu^i(x),j} | \phi_{x,i+j} \rangle = \sum_{j=0}^{d-1} a_{i+j,j}^{x\nu^i(x)} = 0 \quad \forall x \in [N], i \in \{1, \dots, d-1\}. \quad (19)$$

Furthermore, for arbitrary $x, y \in [N]$,

$$\text{Tr}_{\text{anc}}[V|x\rangle\langle y|V^\dagger] = \text{Tr}_{\text{anc}} \left[\sum_{i,j=0}^{d-1} |\nu^i(x)\rangle\langle \nu^j(y)| |\phi_{x,i}\rangle\langle \phi_{y,j}| \right] \quad (20)$$

$$= \sum_{i,j=0}^{d-1} a_{ij}^{xy} |\nu^i(x)\rangle\langle \nu^j(y)| \quad (21)$$

$$= \mathcal{E}(|x\rangle\langle y|). \quad (22)$$

Consequently,

$$\mathcal{E}(\rho) = \text{Tr}_{\text{anc}}[V\rho V^\dagger] \quad (23)$$

for all density matrices ρ , which completes the proof. \square

We refer to the matrix $M_{\mathcal{E}}$ appearing in the proof of [Proposition 1](#) as the Gram matrix of \mathcal{E} :

Definition 3. *Given an invariantly d -sparse Lindbladian \mathcal{L} and a time $t > 0$, the Choi matrix of $\mathcal{E} = e^{\mathcal{L}t}$ can be written as*

$$J(\mathcal{E}) = \sum_{x,y=0}^{N-1} \left(\sum_{i,j=0}^{d-1} a_{ij}^{xy} |\nu^i(x)\rangle\langle\nu^j(y)| \right) \otimes |x\rangle\langle y|. \quad (24)$$

Then the Gram matrix of \mathcal{E} is

$$M_{\mathcal{E}} := \sum_{x,y=0}^{N-1} \left(\sum_{i,j=0}^{d-1} a_{ij}^{xy} |i\rangle\langle j| \right) \otimes |x\rangle\langle y|. \quad (25)$$

2.3 Product formulas for Markovian quantum dynamics

Product formulas are a useful tool for Hamiltonian simulation because they ensure the additivity of efficient Hamiltonian simulation: if H_1 and H_2 can be efficiently simulated, then $H_1 + H_2$ can be efficiently simulated. In particular, reference [\[6\]](#) has carefully analyzed the complexity of Hamiltonian simulation using high-order Suzuki product formulas [\[36, 37\]](#).

Often the spectral norm is applied to characterize the magnitude of Hamiltonians or the distance between the unitary evolutions they generate. While the diamond norm has a clearer operational meaning, the spectral norm distance suffices to characterize unitary dynamics since it is within a constant factor of the diamond norm distance [\[10, Lemma 7\]](#). Recall that the diamond norm is defined as follows:

Definition 4 ([\[26\]](#)). *Let \mathcal{T} be a superoperator in $\mathcal{L}(\mathcal{L}(\mathbb{C}^N))$, where $\mathcal{L}(X)$ is the set of linear operators acting on the space X . Define the diamond norm of \mathcal{T} as*

$$\|\mathcal{T}\|_{\diamond} := \max_{\|\rho\|_1=1} \|\mathcal{T} \otimes \mathcal{I}_N(\rho)\|_1, \quad (26)$$

where $\|\cdot\|_1$ is the trace norm (i.e., the sum of the absolute values of the eigenvalues), \mathcal{I}_N is the identity superoperator in $\mathcal{L}(\mathcal{L}(\mathbb{C}^N))$, and ρ is an arbitrary density matrix in $\mathcal{L}(\mathbb{C}^N)$.

Error estimates for product formulas have been generalized to Markovian quantum dynamics as follows (see also [\[27, Theorem 1\]](#) for a related result for the lowest-order product formula):

Proposition 2 ([\[39\]](#), Theorem 2). *Fix a constant m and let $\mathcal{L}_1, \mathcal{L}_2, \dots, \mathcal{L}_m$ be Lindbladians satisfying $\|\mathcal{L}_1\|_{\diamond} \geq \|\mathcal{L}_2\|_{\diamond} \geq \dots \geq \|\mathcal{L}_m\|_{\diamond}$. For convenience, denote $L_1 := \|\mathcal{L}_1\|_{\diamond}$, $L_2 := \|\mathcal{L}_2\|_{\diamond}$, and $\hat{\mathcal{L}}_i := \mathcal{L}_i/L_1 \forall i \in [m]$. Then for any $k \in \mathbb{N}$ and $0 < \epsilon \leq \min\{1, 4emtL_2\}$ there exists an r such that*

$$\left\| \exp\left(t \sum_{j=1}^m \mathcal{L}_j\right) - [S_{2k}(\hat{\mathcal{L}}_1, \hat{\mathcal{L}}_2, \dots, \hat{\mathcal{L}}_m, t/r)]^{rL_1} \right\|_{\diamond} \leq \epsilon, \quad (27)$$

where S_{2k} is the Suzuki integrator of order k . The number of exponentials of individual terms $\hat{\mathcal{L}}_i$ in the expansion of S_{2k} is at most

$$\frac{4e}{3}(2m-1)m^{1+1/2k}tL_1 \left(\frac{4etL_2}{\epsilon}\right)^{1/2k} \left(\frac{25}{3}\right)^{k-1}. \quad (28)$$

Note that the statement of [Proposition 2](#) in [\[39\]](#) is in terms of the 1-to-1 norm,

$$\|\mathcal{T}\|_{1 \rightarrow 1} := \max_{\|\rho\|_1=1} \|\mathcal{T}(\rho)\|_1, \quad (29)$$

instead of the diamond norm. However, the proof (based on reference [\[33\]](#)) only uses the fact that the 1-to-1 norm of a quantum operation is 1, which is also true for the diamond norm.

[Proposition 2](#) shows that efficient Lindbladian simulation is closed under positive linear combination. In other words, if $\mathcal{L}_1, \mathcal{L}_2, \dots, \mathcal{L}_m$ are (polynomially many) Lindbladians that can be efficiently simulated, then $\sum_{i=1}^m \mathcal{L}_i$ can be efficiently simulated. Note that unlike the case of Hamiltonian simulation, we are restricted to positive linear combinations since Lindbladian dynamics are not in general invertible.

If we can efficiently simulate a Hamiltonian H with corresponding Lindbladian $\mathcal{H}(\rho) = -i[H, \rho]$ and a Lindbladian \mathcal{L} with zero Hamiltonian, then we can efficiently simulate $\mathcal{H} + \mathcal{L}$ by [Proposition 2](#). Thus we assume in the rest of the paper that the Hamiltonian parts of [\(1\)](#), [\(2\)](#), and [\(3\)](#) are zero.

3 Sparse Stinespring isometry framework

3.1 A brief introduction

We now introduce the sparse Stinespring isometry framework, which can efficiently simulate many classes of Lindbladians that are invariantly sparse in the sense of [Definition 1](#).

As in sparse Hamiltonian simulation, the sparse Stinespring isometry framework expresses the Lindbladian as a sum of terms, each of which generates evolution within a low-dimensional subspace. To simulate one such Lindbladian \mathcal{L} acting for time $t > 0$, first we explicitly compute (in superposition) a classical description of the action of the quantum operation $e^{\mathcal{L}t}$ on that low-dimensional subspace. Specifically, we compute the coefficients of the Gram matrix M of $e^{\mathcal{L}t}$ as defined in [Definition 3](#).

Second, we decompose the Gram matrix M into Gram vectors within low-dimensional subspaces. By [Proposition 1](#), the Gram vectors of M are the ancilla states $|\phi_{x,i}\rangle / \|\phi_{x,i}\|$ of a sparse Stinespring isometry V that implements the quantum operation $e^{\mathcal{L}t}$.

Finally, we efficiently implement V by [Theorem 2](#). The implementation has two stages. First we efficiently implement the isometry using an ancilla system; then we efficiently uncompute the ancilla to obtain the correct isometry. As discussed in the introduction, the second step is more technically challenging, as it requires careful application of the orthogonality properties of the Stinespring isometry to uncompute the ancilla without disturbing the effect of the first stage.

The main difficulty in applying the sparse Stinespring isometry framework is to efficiently decompose M into its Gram vectors and to efficiently prepare each Gram vector. We demonstrate how to do this in several cases (namely, local Lindbladians and the first four classes presented in [Table 1](#)).

- In [Theorem 3](#) we show that for a local Lindbladian, this can be done because M has low rank. We present the details in [Algorithm 1](#) in [Appendix A](#).
- In [Theorem 4](#) we show that for an identical-coordinate Lindbladian, this can be done since all matrix elements of the density matrix are invariant under \mathcal{L} , i.e., $\mathcal{L}(|x\rangle\langle y|) \propto |x\rangle\langle y|$.
- In [Lemma 2](#) we show that for a strongly 1-sparse-diagonal Lindbladian with neighbor function ν , this can be done since $\{|u\rangle\langle u|, |\nu(u)\rangle\langle \nu(u)|\}$ is a two-dimensional invariant subspace for any u , and all off-diagonal terms are invariant. This facilitates the simulation of sparse-diagonal Lindbladians in [Theorem 5](#).

- In [Theorem 6](#) we show that for a certain type of dense-diagonal Lindbladian defined by a set of coefficients $\{a_k\}$, this can be done since $\{|u\rangle\langle u|, \frac{\sum a_k |k\rangle\langle k|}{\sum a_k}\}$ is a two-dimensional invariant subspace for any u .
- In [Theorem 7](#) we show that for a 1-ket-sparse Lindbladian with neighbor function ν , this can be done since $\{|u\rangle\langle u|, |u\rangle\langle \nu(u)|, |\nu(u)\rangle\langle u|, |\nu(u)\rangle\langle \nu(u)|\}$ is a four-dimensional invariant subspace for any u , and all other terms are invariant.

3.2 Efficient implementation of d -sparse Stinespring isometries

The following theorem gives a quantum algorithm to implement a sparse Stinespring isometry given the ability to efficiently prepare its Gram vectors:

Theorem 2. *Let \mathcal{E} be an invariantly d -sparse quantum operation as in [Definition 1](#), and denote its d -sparse Stinespring isometry by V where $V|x\rangle = \sum_{i=0}^{r_x-1} |\nu^i(x)\rangle |\phi_{x,i}\rangle$ as in [Definition 2](#). Suppose we are given a black box that outputs S_x on input x . Furthermore, suppose that $|\phi_{x,i}\rangle / \|\phi_{x,i}\|$ can be prepared by $O(c_\phi)$ 2-qubit gates for arbitrary $x \in [N]$, $i \in [r_x]$. Then \mathcal{E} can be implemented by $O(d^2(\log N + c_\phi))$ 2-qubit gates and $O(1)$ queries to the black box.*

Without loss of generality, we can assume that $r_x = d$ for any x since the proof is identical if $r_x < d$.

It suffices to show that for each x , we can implement a unitary gate U_{S_x} acting as

$$U_{S_x} |\nu^k(x)\rangle |0\rangle = \sum_{j=0}^{d-1} |\nu^{j+k}(x)\rangle |\phi_{\nu^k(x),j}\rangle \quad \forall k \in [d] \quad (30)$$

using $O(d^2(\log N + c_\phi))$ 2-qubit gates. Then we can implement the following procedure:

$$|x\rangle |0\rangle \xrightarrow{\text{compute}} |x\rangle |0\rangle |S_x\rangle |U_{S_x}\rangle \quad (31)$$

$$\xrightarrow{\text{by (30)}} U_{S_x} |x\rangle |0\rangle |S_x\rangle |U_{S_x}\rangle \quad (32)$$

$$\xrightarrow{\text{uncompute}} U_{S_x} |x\rangle |0\rangle = \sum_{j=0}^{d-1} |\nu^j(x)\rangle |\phi_{x,i}\rangle, \quad (33)$$

where $|U_{S_x}\rangle$ represents a classical description of U_{S_x} and $|S_x\rangle$ is computed/uncomputed by the black box.

We implement U_{S_x} by a two-stage quantum circuit. First we prepare a unitary U_{\rightarrow} such that for each $k \in [d]$,

$$U_{\rightarrow} |0\rangle |\nu^k(x)\rangle |0\rangle = \sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle. \quad (34)$$

Then we uncompute the ancilla: we implement a unitary U_{\leftarrow} such that for each $k \in [d]$,

$$U_{\leftarrow} \sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle = \sum_{i=0}^{d-1} |0\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle. \quad (35)$$

After both steps, we have

$$U_{\leftarrow} U_{\rightarrow} |0\rangle |\nu^k(x)\rangle |0\rangle = |0\rangle \sum_{j=0}^{d-1} |\nu^{j+k}(x)\rangle |\phi_{\nu^k(x),j}\rangle \quad \forall k \in [d], \quad (36)$$

which gives the unitary U_{S_x} that we want to implement.

3.3 Proof of Theorem 2

3.3.1 Notations

By assumption, for arbitrary $k, i \in [d]$ there exists a unitary gate $\Phi_{\nu^k(x),i}$ satisfying

$$\Phi_{\nu^k(x),i}|0\rangle = \frac{|\phi_{\nu^k(x),i}\rangle}{\| |\phi_{\nu^k(x),i}\rangle \|}, \quad (37)$$

where $\Phi_{\nu^k(x),i}$ can be implemented by $O(c_\phi)$ 2-qubit gates.

In addition, for each $x \in [d]$ we define a unitary gate W_x acting as

$$W_x|0\rangle = \sum_{i=0}^{d-1} \| |\phi_{x,i}\rangle \| |i\rangle. \quad (38)$$

This gate can be implemented using $O(d)$ 2-qubit gates [34].

For any $x \in [N]$ and any unitary gate U , let $\wedge_x(U) := |x\rangle\langle x| \otimes U + (I - |x\rangle\langle x|) \otimes I$ be the gate that performs U on the target register when the control register is in the state $|x\rangle$. See Figure 1 for an example.

Figure 1: The gate $\wedge_x(U)$ with $x = 101$.

More generally, we consider unitary gates that are also controlled on a given quantum state. For any $x \in [N]$, quantum state $|\phi\rangle$, and unitary gate U , let $\wedge_{x,|\phi\rangle}(U) := |x\rangle\langle x| \otimes |\phi\rangle\langle\phi| \otimes U + (I - |x\rangle\langle x| \otimes |\phi\rangle\langle\phi|) \otimes I$ be the gate that performs U on the target register only if the first control register is $|x\rangle$ and the second control register is in the state $|\phi\rangle$. An implementation of such a gate is shown in Figure 2, where Φ is a unitary operation satisfying $\Phi|0\rangle = |\phi\rangle$. We analogously define $\wedge_{|\phi\rangle}(U) := |\phi\rangle\langle\phi| \otimes I + (I - |\phi\rangle\langle\phi|) \otimes I$ (i.e., the application of U is only controlled on the quantum state $|\phi\rangle$).

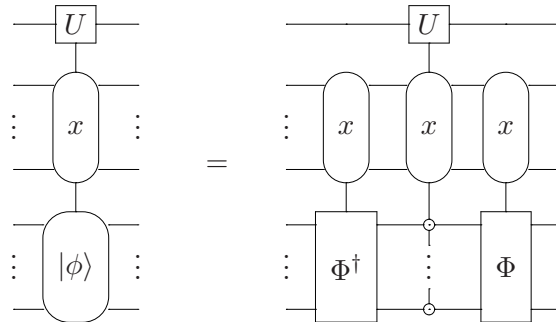

Figure 2: The gate $\wedge_{x,|\phi\rangle}(U)$.

Let $P: [d] \rightarrow [d]$ be the permutation

$$P|j\rangle := |j - 1 \bmod d\rangle \quad \forall j \in [d]. \quad (39)$$

Furthermore, for arbitrary $k \in [d]$, define

$$|\Phi_{x,k}\rangle := \sum_{i=0}^{d-1} |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle. \quad (40)$$

Since $|\phi_{\nu^k(x),i}\rangle / \|\phi_{\nu^k(x),i}\rangle\|$ can be prepared by $O(c_\phi)$ 2-qubit gates for each i and k , the state $|\Phi_{x,k}\rangle$ can be prepared by $O(dc_\phi)$ 2-qubit gates for each k .

Using the controlled gates defined above, for each $k \in \{1, 2, \dots, d-1\}$ we define

$$\begin{aligned} \tilde{U}_{x,k} := & \wedge_{\nu^k(x), |\phi_{\nu^k(x),0}\rangle} (P^{-k}) \wedge_{\nu^{k+1}(x), |\phi_{\nu^k(x),1}\rangle} (P^{-(k+1)}) \cdots \wedge_{\nu^{d-1}(x), |\phi_{\nu^k(x),d-1}\rangle} (P^{-(d-1)}) \\ & \wedge_{|\Phi_{x,k}\rangle} (P^{-k}) \wedge_{\nu^{k-1}(x), |\phi_{\nu^k(x),d-1}\rangle} (P^{k-1}) \cdots \wedge_{\nu^{k+1}(x), |\phi_{\nu^k(x),1}\rangle} (P^{k+1}) \wedge_{\nu^k(x), |\phi_{\nu^k(x),0}\rangle} (P^k), \end{aligned} \quad (41)$$

as shown in [Figure 3](#).

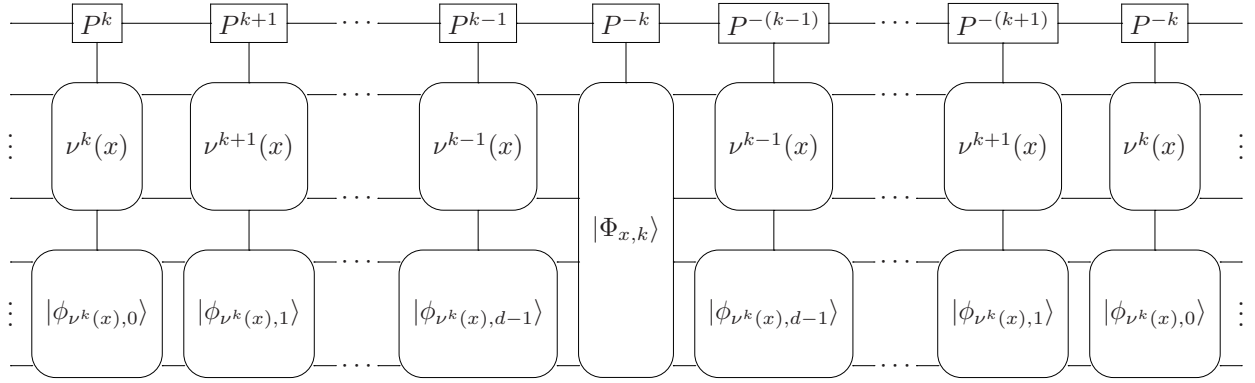

Figure 3: The quantum circuit for $\tilde{U}_{x,k}$.

3.3.2 Proof

Proof of Theorem 2. Define U_{\rightarrow} and U_{\leftarrow} to be the quantum circuits shown in [Figure 4](#) and [Figure 5](#), respectively.

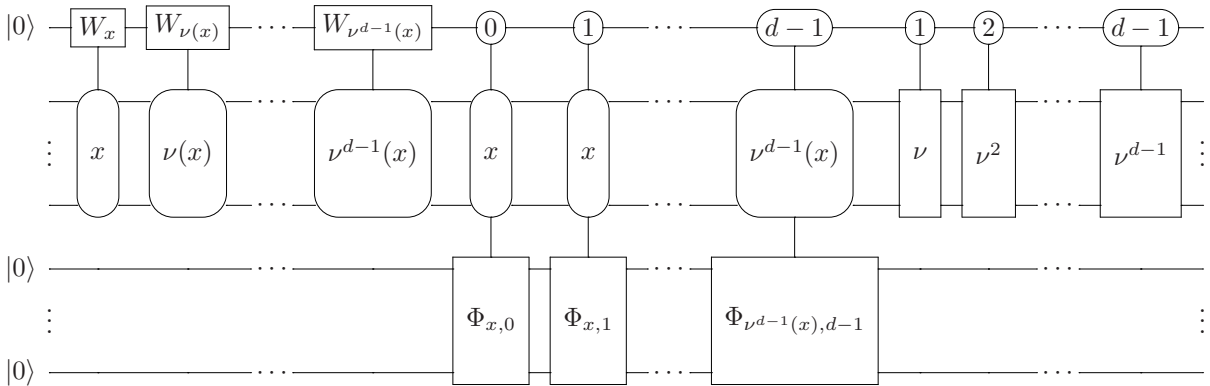

Figure 4: The quantum circuit for U_{\rightarrow} .

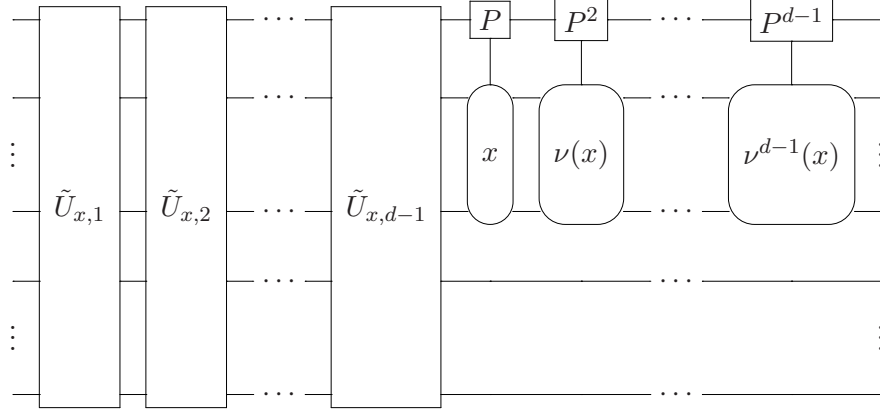

Figure 5: The quantum circuit for U_{\leftarrow} .

We show below that $U_{\leftarrow}U_{\rightarrow}$ satisfies (36). Using the explicit implementations of U_{\rightarrow} and U_{\leftarrow} shown above, the desired unitary U_{S_x} in (30) can be implemented efficiently.

First consider U_{\rightarrow} . It has the effect claimed in (34) because for any $k \in [d]$, it acts as

$$|0\rangle|\nu^k(x)\rangle|0\rangle \xrightarrow{\wedge_{\nu^k(x)}(W_{\nu^k(x)})} \sum_{i=0}^{d-1} ||\phi_{\nu^k(x),i}\rangle||i\rangle|\nu^k(x)\rangle|0\rangle \quad (42)$$

$$\xrightarrow{\Phi_{\nu^k(x),0}, \dots, \Phi_{\nu^k(x),d-1}} \sum_{i=0}^{d-1} |i\rangle|\nu^k(x)\rangle|\phi_{\nu^k(x),i}\rangle \quad (43)$$

$$\xrightarrow{\nu, \dots, \nu^{d-1}} \sum_{i=0}^{d-1} |i\rangle|\nu^{i+k}(x)\rangle|\phi_{\nu^k(x),i}\rangle. \quad (44)$$

Now we show that U_{\leftarrow} has the effect claimed in (35). First observe that, by (8), for each $k \in \{1, 2, \dots, d-1\}$ we have

$$\text{Tr}[\mathcal{E}(|\nu^k(x)\rangle\langle x|)] = 0 \quad \Rightarrow \quad \sum_{j=0}^{d-1} \langle \phi_{x,j+k} | \phi_{\nu^k(x),j} \rangle = 0. \quad (45)$$

On the one hand, applying $\tilde{U}_{x,1}$ to $\sum_{i=0}^{d-1} |i\rangle|\nu^{i+1}(x)\rangle|\phi_{\nu(x),i}\rangle$ gives

$$\sum_{i=0}^{d-1} |i\rangle|\nu^{i+1}(x)\rangle|\phi_{\nu(x),i}\rangle \xrightarrow{\wedge_{\nu(x),|\phi_{\nu(x),0}\rangle}(P^1)} |-1\rangle|\nu(x)\rangle|\phi_{\nu(x),0}\rangle + \sum_{i=1}^{d-1} |i\rangle|\nu^{i+1}(x)\rangle|\phi_{\nu(x),i}\rangle \quad (46)$$

\vdots

$$\xrightarrow{\wedge_{\nu^0(x),|\phi_{\nu(x),d-1}\rangle}(P^0)} |-1\rangle \sum_{i=0}^{d-1} |\nu^{i+1}(x)\rangle|\phi_{\nu(x),i}\rangle = |-1\rangle|\Phi_{x,1}\rangle \quad (47)$$

$$\xrightarrow{\wedge_{|\Phi_{x,1}\rangle}(P^{-1})} |0\rangle \sum_{i=0}^{d-1} |\nu^{i+1}(x)\rangle|\phi_{\nu(x),i}\rangle \quad (48)$$

$$\xrightarrow{\wedge_{\nu^0(x),|\phi_{\nu(x),d-1}\rangle}(P^{-0})} \sum_{i=0}^{d-2} |0\rangle|\nu^{i+1}(x)\rangle|\phi_{\nu(x),i}\rangle + |d\rangle|\nu^d(x)\rangle|\phi_{\nu(x),d-1}\rangle \quad (49)$$

$$\begin{aligned} & \vdots \\ & \xrightarrow{\wedge_{\nu(x), |\phi_{\nu(x),0}\rangle} (P^{-1})} \sum_{i=0}^{d-2} |i+1\rangle |\nu^{i+1}(x)\rangle |\phi_{\nu(x),i}\rangle. \end{aligned} \quad (50)$$

In other words,

$$\tilde{U}_{x,1} \sum_{i=0}^{d-1} |i\rangle |\nu^{i+1}(x)\rangle |\phi_{\nu(x),i}\rangle = \sum_{i=0}^{d-1} |i+1\rangle |\nu^{i+1}(x)\rangle |\phi_{\nu(x),i}\rangle. \quad (51)$$

On the other hand, for any $k \neq 1$, the circuit before the $\wedge_{|\Phi_{x,1}\rangle} (P^{-1})$ gate in $\tilde{U}_{x,1}$ maps $\sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle$ to

$$\begin{aligned} \sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle &= \sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle |\phi_{\nu(x),i+k-1}\rangle \\ &\quad + \sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle (|\phi_{\nu^k(x),i}\rangle - \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle |\phi_{\nu(x),i+k-1}\rangle) \end{aligned} \quad (52)$$

$$\begin{aligned} &\mapsto |-1\rangle \sum_{i=0}^{d-1} |\nu^{i+k}(x)\rangle \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle |\phi_{\nu(x),i+k-1}\rangle \\ &\quad + \sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle (|\phi_{\nu^k(x),i}\rangle - \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle |\phi_{\nu(x),i+k-1}\rangle). \end{aligned} \quad (53)$$

By (45),

$$\langle \Phi_{x,1} | \left(\sum_{i=0}^{d-1} |\nu^{i+k}(x)\rangle \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle |\phi_{\nu(x),i+k-1}\rangle \right) = \sum_{i=0}^{d-1} \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle = 0. \quad (54)$$

Furthermore,

$$\begin{aligned} &\langle \Phi_{x,1} | (|\nu^{i+k}(x)\rangle (|\phi_{\nu^k(x),i}\rangle - \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle |\phi_{\nu(x),i+k-1}\rangle)) \\ &= \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle - \langle \phi_{\nu(x),i+k-1} | \phi_{\nu^k(x),i} \rangle = 0. \end{aligned} \quad (55)$$

Therefore, by (54) and (55) we know that the $\wedge_{|\Phi_{x,1}\rangle} (P^{-1})$ gate in $\tilde{U}_{x,1}$ does not change the state in (53). Finally, the part of $\tilde{U}_{x,1}$ after the $\wedge_{|\Phi_{x,1}\rangle} (P^{-1})$ gate in $\tilde{U}_{x,1}$ maps (53) back to $\sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle$.

Consequently, $\tilde{U}_{x,1}$ maps $\sum_{i=0}^{d-1} |i\rangle |\nu^{i+1}(x)\rangle |\phi_{\nu(x),i}\rangle$ to $\sum_{i=0}^{d-1} |i+1\rangle |\nu^{i+1}(x)\rangle |\phi_{\nu(x),i}\rangle$, while all other $d-1$ possible inputs $\sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle$ (for $k \neq 1$) remain fixed. The same happens for all $\tilde{U}_{x,k}$ with $k \in \{1, \dots, d-1\}$. Thus the overall effect of U_{\leftarrow} is

$$\sum_{i=0}^{d-1} |i\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle \xrightarrow{\tilde{U}_{x,1}, \dots, \tilde{U}_{x,d-1}} \sum_{i=0}^{d-1} |i+k\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle \quad (56)$$

$$\xrightarrow{\wedge_x(P), \dots, \wedge_{\nu^{d-1}(x)}(P^{d-1})} \sum_{i=0}^{d-1} |0\rangle |\nu^{i+k}(x)\rangle |\phi_{\nu^k(x),i}\rangle, \quad (57)$$

which is the claimed output, (35). Therefore, by (34) and (35), we have

$$U_{\leftarrow} U_{\rightarrow} |0\rangle |\nu^k(x)\rangle |0\rangle = |0\rangle \sum_{j=0}^{d-1} |\nu^{j+k}(x)\rangle |\phi_{\nu^k(x),j}\rangle \quad \forall k \in [d], \quad (58)$$

as claimed in (36).

By Lemma 7.11 of [4], gates of the form $\wedge_{\nu^{i+k}(x), |\phi_{\nu^k(x),i}\rangle} (P^{i+k})$ can be implemented using $O(\log N + c_\phi)$ 2-qubit gates for each $i \in [d-1]$ and $k \in [d-1]$, and gates of the form $\wedge_{|\Phi_{x,k}\rangle} (P^{-k})$ can be implemented using $O(\log N + dc_\phi)$ 2-qubit gates for each $k \in [d-1]$. As a result, $O(d(\log N + c_\phi)) + O(\log N + dc_\phi) = O(d(\log N + c_\phi))$ 2-qubit gates suffice to implement $\tilde{U}_{x,k}$ for each $k \in [d-1]$, and $O(d^2(\log N + c_\phi))$ 2-qubit gates suffice to implement U_{\leftarrow} . In addition, $O(d^2(\log dN + c_\phi)) + O(d(\log N + d)) = O(d^2(\log N + c_\phi))$ 2-qubit gates suffice to implement U_{\rightarrow} , where we use the fact that $d \leq N$ and $\log dN \leq 2\log N$. Therefore, U_{S_x} can be implemented using $O(d^2(\log N + c_\phi))$ 2-qubit gates. \square

4 Applications of the sparse Stinespring isometry framework

We now apply the sparse Stinespring isometry framework to give simulations of specific classes of Lindbladians. We show how these methods can efficiently simulate local Lindbladians, subsuming previous work [27, 39]. We also give efficient simulations for four classes of nonlocal Lindbladians.

4.1 Local Lindbladians

First we show that our sparse Stinespring isometry framework can efficiently simulate local Lindbladians.

Consider a Lindbladian \mathcal{L} that only acts nontrivially on c qubits of a $(\log N)$ -qubit system. Assuming without loss of generality that it acts on the first c qubits, such a Lindbladian has the form

$$\mathcal{L} = \mathcal{L}_c \otimes \mathcal{I}_{-c}, \quad (59)$$

where \mathcal{L}_c is a Lindbladian on the first c qubits and \mathcal{I}_{-c} is the identity on the remaining $(\log N) - c$ qubits. For arbitrary integer $x \in [N]$ and positive integer c , let x_c denote the first c bits in the binary representation of x , and let x_{-c} denote the remaining $(\log N) - c$ bits. We can efficiently simulate such Lindbladians:

Lemma 1. *A Lindbladian acting nontrivially on at most c qubits can be simulated for any time $t > 0$ using $O(2^{8c} \log N)$ 2-qubit gates.*

Proof. For a Lindbladian of the form (59), for arbitrary $x_c, y_c \in [2^c]$ and $x_{-c}, y_{-c} \in [2^{(\log N)-c}]$, we have

$$\mathcal{L}(|x_c, x_{-c}\rangle \langle y_c, y_{-c}|) \in \mathbb{L}(\mathbb{C}^{2^c}) \otimes |x_{-c}\rangle \langle y_{-c}|. \quad (60)$$

Thus, \mathcal{L} is invariantly 2^c -sparse. Furthermore, the Gram matrix of $e^{\mathcal{L}t}$ has rank 2^{2c} at any time $t > 0$, and its first 2^{2c} rows and columns constitute a principal submatrix. By Algorithm 1 in Appendix A, for any $x \in [N]$ we can prepare the Gram vector v_x as a quantum state in $O(2^{6c})$ time. Finally, by Theorem 2, \mathcal{L} can be simulated for any time $t > 0$ using $O(2^{2c}(\log N + 2^{6c})) = O(2^{8c} \log N)$ 2-qubit gates. \square

A c -local Lindbladian is sum of Lindbladians, each of which acts nontrivially on at most c qubits. Since there are $\binom{\log N}{c}$ different choices of the c qubits, the number of Lindbladians in the sum is at most $\binom{\log N}{c}$. Thus by [Lemma 1](#) and [Proposition 2](#), taking $m = \binom{\log N}{c} \leq (\log N)^c$ and $L_2 \leq L_1 \leq \|\mathcal{L}\|_\diamond$ in [\(28\)](#), we have:

Theorem 3. *For any $k \in \mathbb{N}$, a c -local Lindbladian \mathcal{L} can be efficiently simulated for any time $t > 0$ within error ϵ using*

$$O\left(\tau\left(\frac{\tau}{\epsilon}\right)^{1/2k}\left(\frac{25}{3}\right)^k(16\log N)^{1+c(2+1/2k)}\right) \quad (61)$$

2-qubit gates, where $\tau := \|\mathcal{L}\|_\diamond t$.

4.2 Identical-coordinate Lindbladians

Suppose the matrix A in [\(3\)](#) satisfies

$$A_{(i,i),(i,i)} = a_i \quad \forall i \in [N] \quad (62)$$

$$A_{(i,i),(j,j)} = c_i + c_j \quad \forall i, j \in [N], i \neq j \quad (63)$$

$$A_{(k,l),(k',l')} = 0 \quad \text{otherwise,} \quad (64)$$

where $\{a_i\}_{i=0}^{N-1}$, $\{c_i\}_{i=0}^{N-1}$ are real numbers that satisfy

$$a_i \geq 0 \quad \forall i \in [N] \quad (65)$$

$$|c_i + c_j| \leq \sqrt{a_i a_j} \quad \forall i, j \in [N]. \quad (66)$$

Then we call the corresponding Lindbladian *identical-coordinate*, since nonzero elements can only appear if the two row coordinates are identical, and similarly for their columns. By [\(6\)](#), this property holds if all Lindblad operators are diagonal. Equation [\(229\)](#) is an instance of identical-coordinate Lindbladians.

Identical-coordinate Lindbladians can be efficiently simulated as follows:

Theorem 4. *Given a black box that takes $x \in [N]$ as input and outputs a_x and c_x , the identical-coordinate Lindbladian defined by [\(62\)](#)–[\(66\)](#) can be simulated for any time $t > 0$ using $O(\log N)$ 2-qubit gates and $O(1)$ queries to the black box, with no error.*

Proof. By [\(3\)](#), when $u \neq v$,

$$\mathcal{L}(|u\rangle\langle v|) = -(a_u + a_v - 2(c_u + c_v))|u\rangle\langle v|; \quad (67)$$

when $u = v$,

$$\mathcal{L}(|u\rangle\langle u|) = 0. \quad (68)$$

Therefore, coherences $|u\rangle\langle v|$ with $u \neq v$ decay exponentially in time [\(67\)](#):

$$e^{\mathcal{L}t}(|u\rangle\langle v|) = e^{-(a_u + a_v - 2(c_u + c_v))t}|u\rangle\langle v|. \quad (69)$$

When $u = v$, the state $|u\rangle\langle u|$ is fixed by [\(68\)](#):

$$e^{\mathcal{L}t}(|u\rangle\langle u|) = |u\rangle\langle u|. \quad (70)$$

To implement the Stinespring isometry at time t , it suffices to find ancilla states $\{|\phi_x\rangle\}_{x=0}^{N-1}$ such that for arbitrary $x \neq y$,

$$\langle\phi_x|\phi_x\rangle = 1; \quad (71)$$

$$\langle\phi_x|\phi_y\rangle = e^{-(a_x+a_y-2(c_x+c_y))t}. \quad (72)$$

For convenience, denote

$$b_{x,t} := e^{-(a_x-2c_x)t}. \quad (73)$$

Since $a_x \geq 2c_x$ by assumption, we have $0 \leq b_{x,t} \leq 1$ for arbitrary x and $t > 0$.

Consider the following construction of the ancilla states for each $x \in [N]$:

$$|\phi_x\rangle = b_{x,t}|0 \dots 0\rangle_{1,\dots,n}|0\rangle_{n+1} + \sqrt{1-b_{x,t}^2}|x\rangle_{1,\dots,n}|1\rangle_{n+1}. \quad (74)$$

Clearly (71) and (72) hold. Furthermore, since $|\phi_x\rangle$ lies in a known two-dimensional subspace, it can be prepared using $O(\log N)$ 2-qubit gates for arbitrary x with $O(1)$ queries to the black box. Therefore, by [Theorem 2](#), we can simulate the identical-coordinate Lindbladian using $O(\log N)$ 2-qubit gates. \square

4.3 Diagonal Lindbladians

Next, we consider Lindbladians with diagonal matrix A in (3), i.e., only terms of the form $A_{(k,l),(k,l)}$ can be nonzero. Letting $a_{k,l} := A_{(k,l),(k,l)}$, we see that in this case equation (3) can be simplified to the following form:

$$\mathcal{L}(\rho) = \sum_{k,l=0}^{N-1} a_{k,l} (2\langle l|\rho|l\rangle|k\rangle\langle k| - |l\rangle\langle l|\rho - \rho|l\rangle\langle l|), \quad (75)$$

where $a_{k,l} \geq 0$ for all $k, l \in [N]$. We call such a Lindbladian *diagonal*.

By (75),

$$\mathcal{L}(|u\rangle\langle u|) = 2 \sum_{k=0}^{N-1} a_{k,u} (|k\rangle\langle k| - |u\rangle\langle u|) \quad \forall u \quad (76)$$

$$\mathcal{L}(|u\rangle\langle v|) = - \sum_{k=0}^{N-1} (a_{k,u} + a_{k,v}) |u\rangle\langle v| \quad \forall u \neq v. \quad (77)$$

Intuitively, (76) shows that diagonal terms follow a classical continuous-time Markov process, while (77) shows that off-diagonal terms simply decay.

4.3.1 Sparse-diagonal Lindbladians

If the matrix a with entries $a_{k,l}$ for $k, l \in [N]$ is d -sparse (i.e., both row d -sparse and column d -sparse), where $d \in \mathbb{N}$ is a fixed constant, we say that \mathcal{L} is *d-sparse-diagonal*. Such Lindbladians can be efficiently simulated:

Theorem 5. *If the matrix a is d -sparse, then given a black box for a that takes a row index or column index as input and outputs all nonzero entries in that row/column together with their positions, the Lindbladian defined by (75) can be simulated for any time $t > 0$ within error ϵ using*

$$O\left(d^{4+1/k} \tau \left(\frac{\tau}{\epsilon}\right)^{1/2k} \left(\frac{25}{3}\right)^k \log N\right) \quad (78)$$

2-qubit gates and $O\left(d^{4+1/k} \tau \left(\frac{\tau}{\epsilon}\right)^{1/2k} \left(\frac{25}{3}\right)^k\right)$ queries to the black box, where $k \in \mathbb{N}$ and $\tau := \|\mathcal{L}\|_\diamond t$.

First consider the special case where the matrix a is *strongly 1-sparse*, i.e., there exists an involution ν such that for all $x \in [N]$, $a_{x,y} \neq 0$ only if $y \in \{x, \nu(x)\}$. Letting $G = (V, E)$ be the underlying undirected graph of a , where rows/columns represent vertices and $(v_x, v_y) \in E$ if and only if $a_{x,y} \neq 0$, then G consists only of isolated vertices (if $\nu(x) = x$, v_x is an isolated vertex) and isolated edges (if $\nu(x) \neq x$, $(x, \nu(x)) \in E$ and $x, \nu(x)$ have no other neighbors). We call ν the neighbor function as in Definition 2. We first show Theorem 5 in this special case:

Lemma 2. *Suppose the matrix a is strongly 1-sparse and we are given a black box for the matrix a that takes input $x \in [N]$ and outputs $\nu(x)$, $a_{x,x}$, and $a_{\nu(x),x}$. Then the Lindbladian defined by (75) can be simulated for any time $t > 0$ by $O(\log N)$ 2-qubit gates and $O(1)$ queries to the black box, with no error.*

To handle the general case, we show that any d -sparse-diagonal Lindbladian can be decomposed into at most $3d^2$ strongly 1-sparse-diagonal Lindbladians:

Lemma 3. *Every d -sparse-diagonal Lindbladian can be written as the sum of at most $3d^2$ strongly 1-sparse-diagonal Lindbladians with constant overhead in queries using the black box in Theorem 5.*

Proof of Theorem 5. The theorem follows directly from Proposition 2, Lemma 2, and Lemma 3, taking $m = 3d^2$ and $L_2 \leq L_1 \leq \|\mathcal{L}\|_\diamond$ in (28). \square

The proof of Lemma 3 is in Appendix B. We prove Lemma 2 here.

Proof of Lemma 2. By Theorem 2, it suffices to show that for any time $t > 0$, there exists a 1-sparse Stinespring isometry V whose ancilla states can be prepared using $O(\log N)$ 2-qubit gates, such that

$$e^{\mathcal{L}t}(\rho) = \text{Tr}_{\text{anc}}[V\rho V^\dagger]. \quad (79)$$

Without loss of generality, assume $\nu(x) \neq x$ for all $x \in [N]$. Since a is strongly 1-sparse, by (75) we have

$$\mathcal{L}(|x\rangle\langle x|) = 2a_{\nu(x),x}|\nu(x)\rangle\langle\nu(x)| - 2a_{\nu(x),x}|x\rangle\langle x| \quad \forall x; \quad (80)$$

$$\mathcal{L}(|x\rangle\langle y|) = -(a_{\nu(x),x} + a_{\nu(y),y} + a_{x,x} + a_{y,y})|x\rangle\langle y| \quad \forall x \neq y. \quad (81)$$

Because

$$\exp\left[\begin{pmatrix} -\alpha & \alpha \\ \beta & -\beta \end{pmatrix} t\right] = \begin{pmatrix} \frac{\beta}{\alpha+\beta} + \frac{\alpha}{\alpha+\beta}e^{-(\alpha+\beta)t} & \frac{\alpha}{\alpha+\beta} - \frac{\alpha}{\alpha+\beta}e^{-(\alpha+\beta)t} \\ \frac{\beta}{\alpha+\beta} - \frac{\beta}{\alpha+\beta}e^{-(\alpha+\beta)t} & \frac{\alpha}{\alpha+\beta} + \frac{\beta}{\alpha+\beta}e^{-(\alpha+\beta)t} \end{pmatrix}, \quad (82)$$

(80) implies

$$\begin{aligned} e^{\mathcal{L}t}(|x\rangle\langle x|) &= \left(\frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}}e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t}\right)|x\rangle\langle x| \\ &\quad + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}}(1 - e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t})|\nu(x)\rangle\langle\nu(x)|. \end{aligned} \quad (83)$$

By (81), we have

$$e^{\mathcal{L}t}(|x\rangle\langle y|) = e^{-(a_{\nu(x),x} + a_{\nu(y),y} + a_{x,x} + a_{y,y})t} |x\rangle\langle y| \quad \forall x \neq y. \quad (84)$$

By Definition 2, it suffices to find ancilla states $\{|\phi_{x,1}\rangle, |\phi_{x,2}\rangle\}_{x=0}^{N-1}$ such that for arbitrary $x \neq y$,

$$\langle\phi_{x,1}|\phi_{x,1}\rangle = \frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t}, \quad (85)$$

$$\langle\phi_{x,2}|\phi_{x,2}\rangle = \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} (1 - e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t}); \quad (86)$$

$$\langle\phi_{x,1}|\phi_{x,2}\rangle = 0; \quad (87)$$

$$\langle\phi_{y,1}|\phi_{x,1}\rangle = e^{-(a_{\nu(x),x} + a_{\nu(y),y} + a_{x,x} + a_{y,y})t}, \quad (88)$$

$$\langle\phi_{y,1}|\phi_{x,2}\rangle = 0; \quad (89)$$

$$\langle\phi_{y,2}|\phi_{x,2}\rangle = 0. \quad (90)$$

Consider the following construction of the ancilla states for each $x \in [N]$:

$$|\phi_{x,1}\rangle = b_x |0 \dots 0\rangle_{1,\dots,n} |1\rangle_{n+1} |0\rangle_{n+2} + c_x |x\rangle_{1,\dots,n} |1\rangle_{n+1} |1\rangle_{n+2} \quad (91)$$

$$|\phi_{x,2}\rangle = a_x |x\rangle_{1,\dots,n} |0\rangle_{n+1} |0\rangle_{n+2}, \quad (92)$$

where a_x , b_x , and c_x are defined as

$$a_x := \sqrt{\frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} (1 - e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t})} \quad (93)$$

$$b_x := e^{-(a_{\nu(x),x} + a_{x,x})t} \quad (94)$$

$$c_x := \sqrt{\frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t} - e^{-2(a_{\nu(x),x} + a_{x,x})t}} \quad (95)$$

for all $x \in [N]$. The entry inside the square root in c_x is positive because from

$$\begin{aligned} & \frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} e^{2a_{\nu(x),x}t} + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} e^{-2a_{x,\nu(x)}t} \\ & \geq \frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} (1 + 2a_{\nu(x),x}t) + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} (1 - 2a_{x,\nu(x)}t) \end{aligned} \quad (96)$$

$$= 1 \quad (97)$$

$$\geq e^{-2a_{x,x}t}, \quad (98)$$

we have

$$\frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t} \geq e^{-2(a_{\nu(x),x} + a_{x,x})t}. \quad (99)$$

The definitions of $|\phi_{x,1}\rangle$ and $|\phi_{x,2}\rangle$ as in (91) and (92) directly give (86)–(90). As for (85), we have

$$\langle\phi_{x,1}|\phi_{x,1}\rangle = b_x^2 + c_x^2 \quad (100)$$

$$= \frac{a_{x,\nu(x)}}{a_{x,\nu(x)} + a_{\nu(x),x}} + \frac{a_{\nu(x),x}}{a_{x,\nu(x)} + a_{\nu(x),x}} e^{-2(a_{x,\nu(x)} + a_{\nu(x),x})t}. \quad (101)$$

In addition, $\|\phi_{x,1}\|^2 + \|\phi_{x,2}\|^2 = 1$ and $\langle \phi_{\nu(x),2} | \phi_{x,1} \rangle + \langle \phi_{\nu(x),1} | \phi_{x,2} \rangle = 0$ are satisfied for all x . Therefore, (91) and (92) give a construction of the 1-sparse Stinespring isometry as claimed.

The state $|\phi_{x,2}\rangle/\|\phi_{x,2}\|$ can be directly prepared using $O(\log N)$ 2-qubit gates. The state $|\phi_{x,1}\rangle/\|\phi_{x,1}\|$ can be prepared by $O(\log N)$ 2-qubit gates and $O(1)$ queries using the following procedure:

$$\begin{aligned} & |0 \dots 0\rangle_{1,\dots,n} |0\rangle_{n+1} |0\rangle_{n+2} \\ & \mapsto \frac{1}{\sqrt{b_x^2 + c_x^2}} (b_x |0 \dots 0\rangle_{1,\dots,n} |1\rangle_{n+1} |0\rangle_{n+2} + c_x |0 \dots 0\rangle_{1,\dots,n} |1\rangle_{n+1} |1\rangle_{n+2}) \end{aligned} \quad (102)$$

$$\mapsto \frac{1}{\sqrt{b_x^2 + c_x^2}} (b_x |0 \dots 0\rangle_{1,\dots,n} |1\rangle_{n+1} |0\rangle_{n+2} + c_x |x\rangle_{1,\dots,n} |1\rangle_{n+1} |1\rangle_{n+2}). \quad (103)$$

This completes the proof. \square

4.3.2 Dense-diagonal Lindbladians

If the matrix a is dense, a counting argument shows it is hard to simulate \mathcal{L} in general. However, we can efficiently simulate \mathcal{L} in the following special case:

Theorem 6. *Suppose the entries of a are independent of the column index, i.e., $a_{k,l} =: a_k$ is independent of l for all k . Then, given a black box that can compute $\sum_{k=k_1}^{k_2} a_k$ for arbitrary $k_1, k_2 \in [N], k_1 \leq k_2$, the Lindbladian \mathcal{L} defined by (75) can be simulated for any time $t > 0$ using $\text{poly}(\log N)$ 2-qubit gates, with no error.*

Observe that, unlike the other simulations we present, Theorem 6 efficiently simulates a set of Lindbladians with full-rank matrices A in (3). In other words, it can efficiently simulate a set of Lindbladians with maximum number of Lindblad operators. Theorem 6 also applies to the special case $A = I_{N^2}$.

Intuitively, if we consider the underlying bipartite graph $G = ((V_R, V_C), E)$ of a where V_R represents the part for rows and V_C represents the part for columns, then G contains N unweighted stars centered in V_R and we can simultaneously simulate all N stars with arbitrary weights on them.

Proof of Theorem 6. For convenience, define

$$S := \sum_{k=0}^{N-1} a_k. \quad (104)$$

By (75), we have

$$\mathcal{L}(|u\rangle\langle v|) = -2S|u\rangle\langle v| \quad \forall u \neq v; \quad (105)$$

$$\mathcal{L}(|u\rangle\langle u|) = 2 \sum_{k=0}^{N-1} a_k |k\rangle\langle k| - 2S|u\rangle\langle u| \quad \forall u. \quad (106)$$

Furthermore, we have

$$\mathcal{L}\left(\sum_{k=0}^{N-1} a_k |k\rangle\langle k|\right) = \sum_{u=0}^{N-1} a_u \left(2 \sum_{k=0}^{N-1} a_k |k\rangle\langle k| - 2S|u\rangle\langle u|\right) = 0. \quad (107)$$

Collecting (106) and (107) into a single vector equation, we have

$$\mathcal{L} \left(\frac{|u\rangle\langle u|}{\sum_{k=0}^{N-1} a_k |k\rangle\langle k|} \right) = \begin{pmatrix} -2S & 2S \\ 0 & 0 \end{pmatrix} \left(\frac{|u\rangle\langle u|}{\sum_{k=0}^{N-1} a_k |k\rangle\langle k|} \right). \quad (108)$$

Because

$$\exp \left[\begin{pmatrix} -2S & 2S \\ 0 & 0 \end{pmatrix} t \right] = \begin{pmatrix} e^{-2St} & 1 - e^{-2St} \\ 0 & 1 \end{pmatrix}, \quad (109)$$

we have

$$e^{\mathcal{L}t}(|u\rangle\langle u|) = e^{-2St}|u\rangle\langle u| + (1 - e^{-2St}) \frac{\sum_{k=0}^{N-1} a_k |k\rangle\langle k|}{S}. \quad (110)$$

Also, by (105), we have

$$e^{\mathcal{L}t}(|u\rangle\langle v|) = e^{-2St}|u\rangle\langle v|. \quad (111)$$

It suffices to efficiently implement an isometry that satisfies (110) and (111).

Consider the isometry $V: \mathbb{C}^N \rightarrow \mathbb{C}^N \otimes \mathbb{C}^N \otimes \mathbb{C}^{N+1}$ defined by

$$V|m\rangle = e^{-St}|m\rangle|0\rangle|0\rangle + \sum_{k=0}^{N-1} \sqrt{\frac{(1 - e^{-2St})a_k}{S}} |k\rangle|k\rangle|m+1\rangle \quad \forall m \in [N], \quad (112)$$

where the second and third subsystems of the output of V are ancilla states. Considering the effect on the third subsystem, we have

$$\text{Tr}_{\text{anc}}[V|m\rangle\langle n|V^\dagger] = e^{-2St}|m\rangle\langle n| \quad \forall m \neq n \quad (113)$$

and

$$\text{Tr}_{\text{anc}}[V|m\rangle\langle m|V^\dagger] = e^{-2St}|m\rangle\langle m| + (1 - e^{-2St}) \frac{\sum_{k=0}^{N-1} a_k |k\rangle\langle k|}{S} \quad \forall m, \quad (114)$$

which match (110) and (111).

The isometry V can be implemented by the quantum circuit in Figure 6. Here, U_1 is a unitary

Figure 6: The quantum circuit for simulating dense-diagonal Lindbladians as in Theorem 6.

acting on an ancilla qubit such that

$$U_1|0\rangle = \sqrt{1 - e^{-2St}}|0\rangle + e^{-St}|1\rangle; \quad (115)$$

the swap gate swaps the state in the first and the third subsystems (the state $|N\rangle$ cannot appear in the third system, so this swap is well-defined); P_1 is a permutation acting on the third subsystem such that

$$P_1|N\rangle = |0\rangle, \quad P_1|k\rangle = |k+1\rangle \quad \forall k \in [N]; \quad (116)$$

U_2 is a unitary gate acting on the second subsystem such that

$$U_2|0\rangle = \sum_{k=0}^{N-1} \sqrt{\frac{a_k}{S}}|k\rangle; \quad (117)$$

and P_2 is a permutation acting on the first and second subsystems such that

$$P_0|0\rangle|k\rangle = |k\rangle|k\rangle \quad \forall k \in \{1, \dots, N-1\}, \quad (118)$$

$$P_0|k\rangle|k\rangle = |0\rangle|k\rangle \quad \forall k \in \{1, \dots, N-1\}, \quad (119)$$

$$P_0|i\rangle|j\rangle = |i\rangle|j\rangle \quad \text{otherwise.} \quad (120)$$

The gates U_1 , P_1 , P_2 , SWAP, and $\wedge_0(\sigma_x)$ (defined in [Figure 1](#)) can be implemented with $\text{poly}(\log N)$ 2-qubit gates using standard techniques. The gate U_2 can be implemented with $\text{poly}(\log N)$ 2-qubit gates using the black box and the method of [\[22\]](#).

Finally, we verify that this quantum circuit gives the isometry V as claimed:

$$|m\rangle|0\rangle|0\rangle|0\rangle \xrightarrow{U_1} |m\rangle|0\rangle|0\rangle(\sqrt{1 - e^{-2St}}|0\rangle + e^{-St}|1\rangle) \quad (121)$$

$$= \sqrt{1 - e^{-2St}}|m\rangle|0\rangle|0\rangle|0\rangle + e^{-St}|m\rangle|0\rangle|0\rangle|1\rangle \quad (122)$$

$$\xrightarrow{\text{SWAP}} \sqrt{1 - e^{-2St}}|0\rangle|0\rangle|m\rangle|0\rangle + e^{-St}|m\rangle|0\rangle|0\rangle|1\rangle \quad (123)$$

$$\xrightarrow{P_1} \sqrt{1 - e^{-2St}}|0\rangle|0\rangle|m+1\rangle|0\rangle + e^{-St}|m\rangle|0\rangle|0\rangle|1\rangle \quad (124)$$

$$\xrightarrow{U_2} \sqrt{1 - e^{-2St}}|0\rangle\left(\sum_{k=0}^{N-1} \sqrt{\frac{a_k}{S}}|k\rangle\right)|m+1\rangle|0\rangle + e^{-St}|m\rangle|0\rangle|0\rangle|1\rangle \quad (125)$$

$$= \sum_{k=0}^{N-1} \sqrt{\frac{(1 - e^{-2St})a_k}{S}}|0\rangle|k\rangle|m+1\rangle|0\rangle + e^{-St}|m\rangle|0\rangle|0\rangle|1\rangle \quad (126)$$

$$\xrightarrow{P_2} \sum_{k=0}^{N-1} \sqrt{\frac{(1 - e^{-2St})a_k}{S}}|k\rangle|k\rangle|m+1\rangle|0\rangle + e^{-St}|m\rangle|0\rangle|0\rangle|1\rangle \quad (127)$$

$$\xrightarrow{\wedge_0(\sigma_x)} \left(\sum_{k=0}^{N-1} \sqrt{\frac{(1 - e^{-2St})a_k}{S}}|k\rangle|k\rangle|m+1\rangle + e^{-St}|m\rangle|0\rangle|0\rangle\right)|0\rangle. \quad (128)$$

This completes the proof. \square

4.4 1-ket-sparse diagonal Lindbladians

In our final application of the sparse Stinespring isometry framework, we consider Lindbladians for which the only nonzero elements of the matrix A in [\(3\)](#) are $a_{k,l} := A_{(k,l),(k,l)}$ and $b_{k,l} := A_{(k,l),(\nu(k),l)}$,

where ν is an involution of $[N]$. As in [Section 4.3.1](#), we call ν the neighbor function. Furthermore, we assume that a and b are also 1-sparse with respect to the same neighbor function ν and that their coefficients satisfy the following relationships:

$$a_{\{x,\nu(x)\}} := a_{x,\nu(x)} = a_{\nu(x),x}, \quad (129)$$

$$a'_{\{x,\nu(x)\}} := a_{x,x} = a_{\nu(x),\nu(x)}, \quad (130)$$

$$b_{\{x,\nu(x)\}} := b_{x,x} = b_{x,\nu(x)} = b_{\nu(x),x} = b_{\nu(x),\nu(x)} \in \mathbb{R}. \quad (131)$$

We call such a Lindbladian *1-ket-sparse* because ν can only act on the first coordinates of both rows and columns, which correspond to the ket vectors in [\(4\)](#). Applying [\(129\)](#), [\(130\)](#), and [\(131\)](#) to [\(3\)](#), we see that 1-ket-sparse Lindbladians have the form

$$\begin{aligned} \mathcal{L}(\rho) = & \sum_{k=0}^{N-1} a_{\{k,\nu(k)\}} (2\langle \nu(k) | \rho | \nu(k) \rangle |k\rangle\langle k| - |\nu(k)\rangle\langle \nu(k)| \rho - \rho |\nu(k)\rangle\langle \nu(k)|) \\ & + \sum_{k=0}^{N-1} a'_{\{k,\nu(k)\}} (2\langle k | \rho | k \rangle |k\rangle\langle k| - |k\rangle\langle k| \rho - \rho |k\rangle\langle k|) \\ & + 2 \sum_{k=0}^{N-1} b_{\{k,\nu(k)\}} (\langle k | \rho | k \rangle + \langle \nu(k) | \rho | \nu(k) \rangle) |k\rangle\langle \nu(k)|. \end{aligned} \quad (132)$$

We show that 1-ket-sparse Lindbladians can be efficiently simulated:

Theorem 7. *Given a black box that takes $x \in [N]$ as input and outputs $\nu(x)$, $a_{\{x,\nu(x)\}}$, $a'_{\{x,\nu(x)\}}$ and $b_{\{x,\nu(x)\}}$, the corresponding 1-ket-sparse Lindbladian defined by [\(132\)](#) can be simulated for any time $t > 0$ using $O(\log N)$ 2-qubit gates and $O(1)$ queries to the black box, with no error.*

While the class of 1-ket-sparse Lindbladians is somewhat artificial, this result shows that we can efficiently simulate some Lindbladians that include off-diagonal elements, together with a structured diagonal.

Proof of Theorem 7. By [Theorem 2](#), it suffices to show that for any time $t > 0$, there exists an 1-sparse Stinespring isometry V whose ancilla states can be prepared using $O(\log N)$ 2-qubit gates such that

$$e^{\mathcal{L}t}(\rho) = \text{Tr}_{\text{anc}}[V\rho V^\dagger]. \quad (133)$$

Since the matrix A in [\(3\)](#) is a positive semidefinite matrix,

$$b_{\{u,\nu(u)\}}^2 \leq 4a_{\{u,\nu(u)\}}a'_{\{u,\nu(u)\}} \quad \forall u \in [N]. \quad (134)$$

By [\(132\)](#),

$$\mathcal{L}(|u\rangle\langle v|) = -(a_{u,u} + a_{v,v} + a_{\nu(u),u} + a_{\nu(v),v})|u\rangle\langle v| \quad \forall u \neq v; \quad (135)$$

$$\mathcal{L}(|u\rangle\langle u|) = 2a_{\{u,\nu(u)\}}(|\nu(u)\rangle\langle \nu(u)| - |u\rangle\langle u|) + b_{\{u,\nu(u)\}}(|\nu(u)\rangle\langle u| + |u\rangle\langle \nu(u)|) \quad \forall u. \quad (136)$$

Therefore, when $u \notin \{v, \nu(v)\}$, we have

$$e^{\mathcal{L}t}(|u\rangle\langle v|) = e^{-(a_{u,u} + a_{v,v} + a_{\nu(u),u} + a_{\nu(v),v})t} |u\rangle\langle v|. \quad (137)$$

For convenience, fix u and denote

$$a := a_{\{u, \nu(u)\}}, \quad a' := a'_{\{u, \nu(u)\}}, \quad b := b_{\{u, \nu(u)\}}. \quad (138)$$

Let $\vec{V}_{\{u, \nu(u)\}} := (|u\rangle\langle u|, |u\rangle\langle \nu(u)|, |\nu(u)\rangle\langle u|, |\nu(u)\rangle\langle \nu(u)|)^T$. In the subspace spanned by $\vec{V}_{\{u, \nu(u)\}}$, we have

$$\mathcal{L}(\vec{V}_{\{u, \nu(u)\}}) = \begin{pmatrix} -2a & b & b & 2a \\ 0 & -2(a+a') & 0 & 0 \\ 0 & 0 & -2(a+a') & 0 \\ 2a & b & b & -2a \end{pmatrix} \vec{V}_{\{u, \nu(u)\}}. \quad (139)$$

Solving the differential equation $\frac{d\rho}{dt} = \mathcal{L}(\rho)$, we get

$$e^{\mathcal{L}t}(\vec{V}_{\{u, \nu(u)\}}) = \begin{pmatrix} \frac{1}{2}(1 + e^{-4at}) & \frac{b(1 - e^{-2(a+a')t})}{2(a+a')} & \frac{b(1 - e^{-2(a+a')t})}{2(a+a')} & \frac{1}{2}(1 - e^{-4at}) \\ 0 & e^{-2(a+a')t} & 0 & 0 \\ 0 & 0 & e^{-2(a+a')t} & 0 \\ \frac{1}{2}(1 - e^{-4at}) & \frac{b(1 - e^{-2(a+a')t})}{2(a+a')} & \frac{b(1 - e^{-2(a+a')t})}{2(a+a')} & \frac{1}{2}(1 + e^{-4at}) \end{pmatrix} \vec{V}_{\{u, \nu(u)\}}. \quad (140)$$

Therefore, for all $u \in [N]$, we have

$$\begin{aligned} e^{\mathcal{L}t}(|u\rangle\langle u|) &= \frac{1}{2}(1 + e^{-4at})|u\rangle\langle u| + \frac{1}{2}(1 - e^{-4at})|\nu(u)\rangle\langle \nu(u)| \\ &\quad + \frac{b(1 - e^{-2(a+a')t})}{2(a+a')}(|u\rangle\langle \nu(u)| + |\nu(u)\rangle\langle u|). \end{aligned} \quad (141)$$

By (137), (141), and Definition 2, it suffices to find ancilla states $\{|\phi_{u,1}\rangle, |\phi_{u,2}\rangle\}_{x=0}^{N-1}$ such that for arbitrary $u \neq v$,

$$\langle \phi_{u,1} | \phi_{u,1} \rangle = \frac{1}{2}(1 + e^{-4at}); \quad (142)$$

$$\langle \phi_{u,2} | \phi_{u,2} \rangle = \frac{1}{2}(1 - e^{-4at}); \quad (143)$$

$$\langle \phi_{u,1} | \phi_{u,2} \rangle = \frac{b(1 - e^{-2(a+a')t})}{2(a+a')}; \quad (144)$$

$$\langle \phi_{v,1} | \phi_{u,1} \rangle = e^{-(a_{\{\nu(u), u\}} + a_{\{\nu(v), v\}} + a_{\{u, u\}} + a_{\{v, v\}})t}; \quad (145)$$

$$\langle \phi_{v,1} | \phi_{u,2} \rangle = 0; \quad (146)$$

$$\langle \phi_{v,2} | \phi_{u,2} \rangle = 0. \quad (147)$$

Consider the following construction of the ancilla states for all $u \in [N]$:

$$|\phi_{u,1}\rangle = b_u |0 \dots 0\rangle_{1, \dots, n} |1\rangle_{n+1} |0\rangle_{n+2} + c_u |u\rangle_{1, \dots, n} |1\rangle_{n+1} |1\rangle_{n+2}; \quad (148)$$

$$|\phi_{u,2}\rangle = \frac{d_u}{c_u} |u\rangle_{1, \dots, n} |1\rangle_{n+1} |1\rangle_{n+2} + \sqrt{a_u^2 - \frac{d_u^2}{c_u^2}} |u\rangle_{1, \dots, n} |0\rangle_{n+1} |0\rangle_{n+2}, \quad (149)$$

with

$$a_u := \sqrt{\frac{1}{2}(1 - e^{-4at})} \quad (150)$$

$$b_u := e^{-(a+a')t} \quad (151)$$

$$c_u := \sqrt{\frac{1}{2}(1 + e^{-4at} - 2e^{-2(a+a')t})} \quad (152)$$

$$d_u := \frac{b(1 - e^{-2(a+a')t})}{2(a + a')}. \quad (153)$$

For any $a, a', t > 0$, one can show that

$$(1 - e^{-4at})(1 + e^{-4at} - 2e^{-2(a+a')t}) \geq \frac{4aa'}{(a + a')^2}(1 - e^{-2(a+a')t})^2. \quad (154)$$

By (134) and (154), we have

$$a_u^2 c_u^2 \geq d_u^2. \quad (155)$$

If $c_u = 0$, then by (155) we must have $d_u = 0$. In this case, we simply define $\frac{d_u^2}{c_u^2} := 0$ in (149).

The definitions of $|\phi_{u,1}\rangle$ and $|\phi_{u,2}\rangle$ as in (148) and (149) directly give (144)–(147). As for (142) and (143), we have

$$\langle \phi_{u,1} | \phi_{u,1} \rangle = b_u^2 + c_u^2 = e^{-2(a+a')t} + \frac{1}{2}(1 + e^{-4at} - 2e^{-2(a+a')t}) = \frac{1}{2}(1 + e^{-4at}); \quad (156)$$

$$\langle \phi_{u,2} | \phi_{u,2} \rangle = \frac{d_u^2}{c_u^2} + (a_u^2 - \frac{d_u^2}{c_u^2}) = a_u^2 = \frac{1}{2}(1 - e^{-4at}). \quad (157)$$

In addition, for all $u \in [N]$, $\|\phi_{u,1}\|^2 + \|\phi_{u,2}\|^2 = 1$ by (142) and (143), and $\langle \phi_{\nu(u),2} | \phi_{u,1} \rangle + \langle \phi_{\nu(u),1} | \phi_{u,2} \rangle = 0$ by (146). Therefore, (148) and (149) give a construction of the 1-sparse Stinespring isometry as claimed. Similarly to (103), all these ancilla states can be prepared using $O(\log N)$ 2-qubit gates. \square

5 Sparse Lindblad operators

In this section, we consider simulating a Lindbladian generated by a single Lindblad operator L :

$$\mathcal{L}(\rho) = L\rho L^\dagger - \frac{1}{2}(L^\dagger L\rho + \rho L^\dagger L). \quad (158)$$

Of course, any Lindbladian can be decomposed into a sum of such terms.

We assume that the matrix L in (158) is both row k -sparse and column k -sparse, and $\|L\|_{\max} \leq 1$ (i.e., the largest entry of L in absolute value is bounded by 1), which can always be obtained by rescaling. Under these assumptions, we can efficiently implement a quantum operation \mathcal{E}_ϵ that approximates \mathcal{L} for a short time ϵ up to first order.

Lemma 4. *Suppose we are given a black box for a k -sparse Lindblad operator L that takes a row index or column index as input and outputs all nonzero entries in that row/column and their positions. Then for any $\epsilon > 0$, we can efficiently implement a quantum operation \mathcal{E}_ϵ such that*

$$\|(1 + \epsilon\mathcal{L}) - \mathcal{E}_\epsilon\|_\diamond = O(k^4\epsilon^2). \quad (159)$$

If $k = 1$, we can implement \mathcal{E}_ϵ using $O(\log N)$ 2-qubit gates and $O(1)$ queries, with no error. More generally, for $k \geq 2$, we can implement \mathcal{E}_ϵ using $O(k^2[\log N + \log^{5/2}(k/\epsilon)] \frac{\log(k/\epsilon)}{\log \log(k/\epsilon)})$ 2-qubit gates and $O(k^2 \frac{\log(k/\epsilon)}{\log \log(k/\epsilon)})$ queries.

By concatenating a sequence of short-time evolutions, [Lemma 4](#) implies an efficient simulation of \mathcal{L} for arbitrary times, as follows.

Theorem 8. Suppose we are given a black box for L that takes a row index or column index as input and outputs all nonzero entries in that row/column and their positions. If L is 1-sparse, for any time $t > 0$ we can simulate \mathcal{L} within error ϵ using $O(\frac{t^2 \log N}{\epsilon})$ 2-qubit gates and $O(\frac{t^2}{\epsilon})$ queries. If L is k -sparse with $k \geq 2$, for any time $t > 0$ we can simulate \mathcal{L} within error ϵ using $O(\frac{k^6 t^2}{\epsilon} [\log N + \log^{5/2}(k^5 t/\epsilon)] \frac{\log(k^5 t/\epsilon)}{\log \log(k^5 t/\epsilon)})$ 2-qubit gates and $O(\frac{k^6 t^2}{\epsilon} \frac{\log(k^5 t/\epsilon)}{\log \log(k^5 t/\epsilon)})$ queries.

Proof. By [Lemma 4](#) we have

$$\|(1 + \varepsilon \mathcal{L})^{t/\varepsilon} - \mathcal{E}_\varepsilon^{t/\varepsilon}\|_\diamond = O(k^4 t \varepsilon). \quad (160)$$

By L'Hôpital's rule,

$$\lim_{\varepsilon \rightarrow 0} \frac{e^{\mathcal{L}t} - (1 + \varepsilon \mathcal{L})^{t/\varepsilon}}{\varepsilon} = \frac{d}{d\varepsilon} (e^{\mathcal{L}t} - (1 + \varepsilon \mathcal{L})^{t/\varepsilon}) \Big|_{\varepsilon=0} = \frac{1}{2} t \mathcal{L}^2 e^{\mathcal{L}t}. \quad (161)$$

Therefore,

$$\|e^{\mathcal{L}t} - (1 + \varepsilon \mathcal{L})^{t/\varepsilon}\|_\diamond = \frac{1}{2} \varepsilon t \|\mathcal{L}^2 e^{\mathcal{L}t}\|_\diamond + O(\varepsilon^2). \quad (162)$$

Because L is k -sparse and $\|L\|_{\max} = O(1)$, one can show that $\|\mathcal{L}\|_\diamond = O(k^2)$; since $e^{\mathcal{L}t}$ is a quantum operation, $\|e^{\mathcal{L}t}\|_\diamond = 1$. Thus $\|\mathcal{L}^2 e^{\mathcal{L}t}\|_\diamond \leq \|\mathcal{L}\|_\diamond^2 = O(k^4)$. Therefore, combining [\(160\)](#) and [\(162\)](#), we have

$$\|e^{\mathcal{L}t} - \mathcal{E}_\varepsilon^{t/\varepsilon}\|_\diamond = O(k^4 t \varepsilon). \quad (163)$$

Therefore, if we take $\varepsilon = \epsilon/(tk^4)$, we find

$$\|e^{\mathcal{L}t} - \mathcal{E}_{\epsilon/(tk^4)}^{t^2 k^4/\epsilon}\|_\diamond = O(\epsilon). \quad (164)$$

If $k = 1$, since by [Lemma 4](#) we can implement $\mathcal{E}_{\epsilon/t}$ using $O(\log N)$ 2-qubit gates and $O(1)$ queries, we can repeat it t^2/ϵ times to simulate $e^{\mathcal{L}t}$ within error ϵ using $O(\frac{t^2 \log N}{\epsilon})$ 2-qubit gates and $O(\frac{t^2}{\epsilon})$ queries. If $k \geq 2$, since by [Lemma 4](#) we can implement $\mathcal{E}_{\epsilon/(tk^4)}$ using $O(k^2[\log N + \log^{5/2}(k^5 t/\epsilon)] \frac{\log(k^5 t/\epsilon)}{\log \log(k^5 t/\epsilon)})$ 2-qubit gates and $O(k^2 \frac{\log(k^5 t/\epsilon)}{\log \log(k^5 t/\epsilon)})$ queries, we can repeat it $t^2 k^4/\epsilon$ times to simulate $e^{\mathcal{L}t}$ within error ϵ using $O(\frac{k^6 t^2}{\epsilon} [\log N + \log^{5/2}(k^5 t/\epsilon)] \frac{\log(k^5 t/\epsilon)}{\log \log(k^5 t/\epsilon)})$ 2-qubit gates and $O(\frac{k^6 t^2}{\epsilon} \frac{\log(k^5 t/\epsilon)}{\log \log(k^5 t/\epsilon)})$ queries. \square

When L is 1-sparse, it is straightforward to implement the quantum operation \mathcal{E}_ϵ of [Lemma 4](#), as explained in [Section 5.1](#). More generally, we show how to implement \mathcal{E}_ϵ for any k -sparse L in [Section 5.2](#).

A higher-order version of this construction might lead to improved performance. We leave this as an open problem.

5.1 1-sparse Lindblad operator

Proof of Lemma 4. If L is 1-sparse, there exists a permutation $\nu: [N] \rightarrow [N]$ such that

$$\forall j \in [N] \exists c_j \in \mathbb{C} \text{ such that } L|j\rangle = c_j|\nu(j)\rangle. \quad (165)$$

For $0 < \epsilon \leq 1/\|L\|_{\max}^2$, define the isometry

$$V_\epsilon|m\rangle := \sqrt{1 - \epsilon|c_m|^2}|m\rangle|0\rangle + \sqrt{\epsilon}c_m|\nu(m)\rangle|1\rangle \quad \forall m \in [N]. \quad (166)$$

We show that the quantum operation $\mathcal{E}_\epsilon(\rho) := \text{Tr}_{\text{anc}}[V_\epsilon \rho V_\epsilon^\dagger]$ satisfies Lemma 4. To do this, by subadditivity of the trace norm it suffices to show that for an arbitrary pure state $|\Phi\rangle = \sum_{m,m'=0}^{N-1} b_{mm'}|m\rangle|m'\rangle$ where $\sum_{m,m'=0}^{N-1} |b_{mm'}|^2 = 1$,

$$\|((1 + \epsilon\mathcal{L}) \otimes \mathcal{I}_N)(|\Phi\rangle\langle\Phi|) - \text{Tr}_{\text{anc}}[(V_\epsilon \otimes I_N)|\Phi\rangle\langle\Phi|(V_\epsilon^\dagger \otimes I_N)]\|_1 = O(\epsilon^2). \quad (167)$$

We have $L^\dagger|\nu(j)\rangle = c_j^*|j\rangle \forall j \in [N]$. Thus for any $m, n \in [N]$,

$$(1 + \epsilon\mathcal{L})(|m\rangle\langle n|) = |m\rangle\langle n| + \epsilon(c_m c_n^*|\nu(m)\rangle\langle\nu(n)| - \frac{1}{2}(|c_m|^2 + |c_n|^2)|m\rangle\langle n|). \quad (168)$$

For convenience, denote $l_m := 1 - \sqrt{1 - \epsilon|c_m|^2}$ for each m . By (166) and (168), we have

$$\begin{aligned} (1 + \epsilon\mathcal{L})(|m\rangle\langle n|) - \text{Tr}_{\text{anc}}[V_\epsilon|m\rangle\langle n|V_\epsilon^\dagger] \\ = (1 - \frac{\epsilon}{2}(|c_m|^2 + |c_n|^2) - \sqrt{(1 - \epsilon|c_m|^2)(1 - \epsilon|c_n|^2)})|m\rangle\langle n| \end{aligned} \quad (169)$$

$$= \frac{1}{2}(l_m - l_n)^2|m\rangle\langle n|. \quad (170)$$

Therefore,

$$\begin{aligned} & \|((1 + \epsilon\mathcal{L}) \otimes \mathcal{I}_N)(|\Phi\rangle\langle\Phi|) - \text{Tr}_{\text{anc}}[(V_\epsilon \otimes I_N)|\Phi\rangle\langle\Phi|(V_\epsilon^\dagger \otimes I_N)]\|_1 \\ &= \left\| \sum_{m,m',n,n'} b_{mm'}b_{nn'}^* ((1 + \epsilon\mathcal{L})(|m\rangle\langle n|) - \text{Tr}_{\text{anc}}[V_\epsilon|m\rangle\langle n|V_\epsilon^\dagger]) \otimes |m'\rangle\langle n'| \right\|_1 \end{aligned} \quad (171)$$

$$= \frac{1}{2} \left\| \sum_{n,n'} \left(\sum_{m,m'} b_{mm'}b_{nn'}^* (l_m - l_n)^2 |m\rangle\langle n| \right) \otimes |m'\rangle\langle n'| \right\|_1 \quad (172)$$

$$\leq \left\| \sum_{n,n'} \sum_{m,m'} b_{mm'}b_{nn'}^* l_m^2 |m\rangle\langle n| \otimes |m'\rangle\langle n'| \right\|_1 + \left\| \sum_{n,n'} \sum_{m,m'} b_{mm'}b_{nn'}^* l_m l_n |m\rangle\langle n| \otimes |m'\rangle\langle n'| \right\|_1 \quad (173)$$

$$= \sqrt{\sum_{m,m'} |b_{mm'}|^2 l_m^4} \sqrt{\sum_{n,n'} |b_{nn'}|^2} + \sum_{m,m'} |b_{mm'}|^2 l_m^2 \quad (174)$$

$$= O(\epsilon^2), \quad (175)$$

where the last equality follows from $l_m = O(\epsilon)$ and $\sum_{m,m'=0}^{N-1} |b_{mm'}|^2 = 1$.

The isometry V_ϵ can be implemented by the following procedure:

$$|m\rangle \mapsto |m\rangle(\sqrt{1 - \epsilon|c_m|^2}|0\rangle + \sqrt{\epsilon}c_m|1\rangle) \quad (176)$$

$$\xrightarrow{\text{control}-\nu} \sqrt{1 - \epsilon|c_m|^2}|m\rangle|0\rangle + \sqrt{\epsilon}c_m|\nu(m)\rangle|1\rangle. \quad (177)$$

Here in the first step we compute c_m , prepare the ancilla qubit, and then uncompute c_m . To compute ν in place for the second step, we compute $|m\rangle \mapsto |m\rangle|\nu(m)\rangle$, and then perform the inverse of the map $|\nu(m)\rangle \mapsto |\nu(m)\rangle|\nu(\nu(m))\rangle = |\nu(m)\rangle|m\rangle$ to erase the $|m\rangle$ register. This procedure uses $O(\log N)$ 2-qubit gates and $O(1)$ queries, with no error. \square

5.2 k -sparse Lindblad operator

If L is k -sparse, there exist permutations

$$\nu_1, \nu_2, \dots, \nu_k: [N] \rightarrow [N] \quad (178)$$

such that

$$L|j\rangle = \sum_{i=1}^k c_{j,i} |\nu_i(j)\rangle \quad \forall j \in [N], \quad (179)$$

where

$$\nu_i(x) \neq \nu_j(x) \quad \forall x \in [N], \forall i \neq j. \quad (180)$$

For $0 < \epsilon \leq 1/\|L\|_{\max}^2$, define $V_\epsilon: \mathbb{C}^N \rightarrow \mathbb{C}^N \otimes \mathbb{C}^2$ such that

$$V_\epsilon|m\rangle := \sum_{i=1}^k \sqrt{\epsilon} c_{m,i} |\nu_i(m)\rangle |1\rangle + |m\rangle |0\rangle - \epsilon \sum_{1 \leq i \neq j \leq k} \frac{1}{2} c_{m,i} \cdot c_{\nu_j^{-1}(\nu_i(m)),j}^* |\nu_j^{-1}(\nu_i(m))\rangle |0\rangle \quad (181)$$

and $\mathcal{E}'_\epsilon(\rho) := \text{Tr}_{\text{anc}}[V_\epsilon \rho V_\epsilon^\dagger]$.

The construction of the quantum operation \mathcal{E}_ϵ in [Lemma 4](#) is based on two observations:

Lemma 5. \mathcal{E}'_ϵ approximates $e^{\mathcal{L}t}$ up to first order:

$$\|(1 + \epsilon \mathcal{L}) - \mathcal{E}'_\epsilon\|_\diamond = O(k^4 \epsilon^2). \quad (182)$$

Lemma 6. $V_\epsilon^\dagger V_\epsilon$ approximates the identity up to first order in the spectral norm:

$$\|V_\epsilon^\dagger V_\epsilon - I\| = O(k^4 \epsilon^2). \quad (183)$$

The proofs of [Lemma 5](#) and [Lemma 6](#) are shown in [Section C.1](#) and [Section C.2](#), respectively.

Furthermore, \mathcal{E}'_ϵ can be approximately implemented by a sparse unitary transformation, which follows from a more general proposition:

Proposition 3. Suppose d is a fixed positive integer, and let $V: \mathbb{C}^N \rightarrow \mathbb{C}^N \otimes \mathbb{C}^d$ be a matrix that is both row and column sparse. Furthermore, suppose V is ϵ -close to an isometry, in the sense that

$$\|V^\dagger V - I\| \leq \epsilon. \quad (184)$$

Define the map $\mathcal{E}'(\rho) := \text{Tr}_{\text{anc}}[V \rho V^\dagger]$. Then we can efficiently implement a quantum operation \mathcal{E} such that

$$\|\mathcal{E} - \mathcal{E}'\|_\diamond = O(\epsilon). \quad (185)$$

[Proposition 3](#) shows that we can efficiently implement sparse approximate isometries, generalizing the implementation of sparse unitaries [\[25\]](#).

Proof of [Proposition 3](#). Define

$$H := \begin{pmatrix} 0 & V \\ V^\dagger & 0 \end{pmatrix} \quad (186)$$

to be a Hamiltonian in $\mathbb{C}^{(d+1)^N}$. Consider the quantum operation

$$\mathcal{E}(\rho) := \text{Tr}_{\text{anc}}[e^{-iH\frac{\pi}{2}}(|d\rangle\langle d| \otimes \rho)e^{iH\frac{\pi}{2}}], \quad (187)$$

where \mathcal{E} uses ancilla of dimension $d+1$ and $|d\rangle$ is the $(d+1)$ st state of the computational basis of the ancilla system. \mathcal{E} can be efficiently implemented because H is a sparse Hamiltonian, which can be efficiently simulated. We will show that \mathcal{E} satisfies (185).

By subadditivity of the trace norm, it suffices to prove (185) for pure states, i.e., for any state $|\Phi\rangle = \sum_{m,m'=0}^{N-1} b_{mm'}|m\rangle|m'\rangle$ where $\sum_{m,m'=0}^{N-1} |b_{mm'}|^2 = 1$,

$$\left\| \text{Tr}_{\text{anc}} \left[(e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle\Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N) - (V \otimes I_N)|\Phi\rangle\langle\Phi|(V^\dagger \otimes I_N) \right] \right\|_1 = O(\varepsilon). \quad (188)$$

Furthermore, since $(e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle\Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N)$ and $(V \otimes I_N)|\Phi\rangle\langle\Phi|(V^\dagger \otimes I_N)$ are both rank-1 matrices, $(e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle\Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N) - (V \otimes I_N)|\Phi\rangle\langle\Phi|(V^\dagger \otimes I_N)$ can be at most rank 2. Therefore, its trace norm must be upper-bounded by twice its spectral norm, and thus it suffices to prove

$$\left\| \text{Tr}_{\text{anc}} \left[(e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle\Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N) - (V \otimes I_N)|\Phi\rangle\langle\Phi|(V^\dagger \otimes I_N) \right] \right\| = O(\varepsilon). \quad (189)$$

In turn, this shows that it suffices to prove

$$\left\| (e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle\Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N) - (\tilde{V} \otimes I_N)|\Phi\rangle\langle\Phi|(\tilde{V}^\dagger \otimes I_N) \right\| = O(\varepsilon), \quad (190)$$

where $\tilde{V}: \mathbb{C}^N \rightarrow \mathbb{C}^N \otimes \mathbb{C}^{d+1}$ such that $\tilde{V} = \begin{pmatrix} V \\ 0 \end{pmatrix}$, i.e., the first dN rows of \tilde{V} are identical to V , and the last N rows of \tilde{V} are all 0.

We claim that for any $m, n \in [N]$,

$$\left\| e^{-iH\frac{\pi}{2}}(|d\rangle\langle d| \otimes |m\rangle\langle n|)e^{iH\frac{\pi}{2}} - \tilde{V}|m\rangle\langle n|\tilde{V}^\dagger \right\| = O(\varepsilon). \quad (191)$$

For convenience, denote $P := VV^\dagger$. Then

$$\|P^2 - P\| = \|VV^\dagger VV^\dagger - VV^\dagger\| = \|V(I + O(\varepsilon))V^\dagger - VV^\dagger\| = O(\varepsilon). \quad (192)$$

Furthermore,

$$\|H^3 - H\| = \left\| \begin{pmatrix} 0 & VV^\dagger V \\ V^\dagger VV^\dagger & 0 \end{pmatrix} - \begin{pmatrix} 0 & V \\ V^\dagger & 0 \end{pmatrix} \right\| = \left\| \begin{pmatrix} 0 & VO(\varepsilon) \\ O(\varepsilon)V^\dagger & 0 \end{pmatrix} \right\| = O(\varepsilon). \quad (193)$$

By the same method, we can show that for any positive integer n ,

$$\|H^{n+2}\| = \|H^n\| + O(\varepsilon) \quad (194)$$

where the big- O constant is independent of n .

By (194), for a fixed time $t > 0$ we have

$$\begin{aligned} & \left\| \cos(Ht) - (1 - H^2 + H^2 \cos t) \right\| \\ &= \left\| 1 - \frac{H^2 t^2}{2} + \sum_{n=2}^{\infty} (-1)^n \frac{H^{2n} t^{2n}}{(2n)!} - (1 - \frac{H^2 t^2}{2} + \sum_{n=2}^{\infty} (-1)^n \frac{H^2 t^{2n}}{(2n)!}) \right\| \end{aligned} \quad (195)$$

$$= \left\| \sum_{n=2}^{\infty} (-1)^n \frac{(H^{2n} - H^2) t^{2n}}{(2n)!} \right\| \quad (196)$$

$$\leq \sum_{n=2}^{\infty} \frac{t^{2n} \|H^{2n} - H^2\|}{(2n)!} \quad (197)$$

$$= \sum_{n=2}^{\infty} \frac{t^{2n} n O(\varepsilon)}{(2n)!} \quad (198)$$

$$= O(\varepsilon). \quad (199)$$

A similar calculation shows that

$$\|\sin(Ht) - H \sin t\| = O(\varepsilon). \quad (200)$$

Therefore,

$$\|e^{-iHt} - (1 - H^2 + H^2 \cos t) + iH \sin t\| = O(\varepsilon). \quad (201)$$

Taking $t = \frac{\pi}{2}$ in (201), we have

$$\|e^{-iH\frac{\pi}{2}} - (1 - iH - H^2)\| = O(\varepsilon). \quad (202)$$

As a block matrix, we have

$$1 - iH - H^2 = \begin{pmatrix} I - VV^\dagger & -iV \\ -iV^\dagger & I - V^\dagger V \end{pmatrix}. \quad (203)$$

Plugging (202) and (203) into (191), and by the definition of \tilde{V} , we have

$$\begin{aligned} & \|e^{-iH\frac{\pi}{2}}(|d\rangle\langle d| \otimes |m\rangle\langle n|)e^{iH\frac{\pi}{2}} - \tilde{V}|m\rangle\langle n|\tilde{V}^\dagger\| \\ &= \left\| e^{-iH\frac{\pi}{2}}(|d\rangle\langle d| \otimes |m\rangle\langle n|)e^{iH\frac{\pi}{2}} - \begin{pmatrix} V|m\rangle\langle n|V^\dagger & 0 \\ 0 & 0 \end{pmatrix} \right\| \end{aligned} \quad (204)$$

$$= \left\| \begin{pmatrix} -iV|m\rangle \\ (I - V^\dagger V)|m\rangle \end{pmatrix} \begin{pmatrix} i\langle n|V^\dagger & \langle n|(I - V^\dagger V) \end{pmatrix} - \begin{pmatrix} V|m\rangle\langle n|V^\dagger & 0 \\ 0 & 0 \end{pmatrix} \right\| + O(\varepsilon) \quad (205)$$

$$= \left\| \begin{pmatrix} 0 & -iV|m\rangle\langle n|(I - V^\dagger V) \\ i(I - V^\dagger V)|m\rangle\langle n|V^\dagger & (I - V^\dagger V)|m\rangle\langle n|(I - V^\dagger V) \end{pmatrix} \right\| + O(\varepsilon) \quad (206)$$

$$= O(\varepsilon), \quad (207)$$

where the last equality comes from the assumption that $\|I - V^\dagger V\| = O(\varepsilon)$.

Now, for any $m \in [N]$, let

$$|\Psi_m\rangle := e^{-iH\frac{\pi}{2}}|d\rangle|m\rangle, \quad (208)$$

$$|\Phi_m\rangle := \tilde{V}|m\rangle. \quad (209)$$

Equation (191) ensures that for any normalized pure states $|\gamma_1\rangle, |\gamma_2\rangle \in \mathbb{C}^{d+1} \otimes \mathbb{C}^N$,

$$|\langle\gamma_1|\Psi_m\rangle\langle\Psi_n|\gamma_2\rangle - \langle\gamma_1|\Phi_m\rangle\langle\Phi_n|\gamma_2\rangle| = O(\varepsilon) \quad \forall m, n \in [N]. \quad (210)$$

To prove (190) it suffices to show that for any pure state $|\Gamma\rangle \in \mathbb{C}^{d+1} \otimes \mathbb{C}^N \otimes \mathbb{C}^N$,

$$|\langle\Gamma|((e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle\Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N) - (\tilde{V} \otimes I_N)|\Phi\rangle\langle\Phi|(\tilde{V}^\dagger \otimes I_N))|\Gamma\rangle| = O(\varepsilon). \quad (211)$$

By the Schmidt decomposition, we can write $|\Gamma\rangle = \sum_{m'=0}^{N-1} c_{m'} |\gamma_{m'}\rangle |m'\rangle$ where $|\gamma_{m'}\rangle$ are orthonormal pure states in $\mathbb{C}^{d+1} \otimes \mathbb{C}^N$ for $m' \in [N]$, $c_{m'} \geq 0$ for any $m' \in [N]$, and $\sum_{m'=0}^{N-1} c_{m'}^2 = 1$. Then, (211)

holds because

$$\begin{aligned} & |\langle \Gamma | ((e^{-iH\frac{\pi}{2}} \otimes I_N)(|d\rangle\langle d| \otimes |\Phi\rangle\langle \Phi|)(e^{iH\frac{\pi}{2}} \otimes I_N) - (\tilde{V} \otimes I_N)|\Phi\rangle\langle \Phi|(\tilde{V}^\dagger \otimes I_N)) | \Gamma \rangle| \\ &= \left| \sum_{m,m'} \sum_{n,n'} b_{mm'} b_{nn'}^* c_{m'} c_{n'} (\langle \gamma_{m'} | \Psi_m \rangle \langle \Psi_n | \gamma_{n'} \rangle - \langle \gamma_{m'} | \Phi_m \rangle \langle \Phi_n | \gamma_{n'} \rangle) \right| \end{aligned} \quad (212)$$

$$\leq \sum_{m,m'} \sum_{n,n'} |b_{mm'} b_{nn'}^* c_{m'} c_{n'}| \cdot |\langle \gamma_{m'} | \Psi_m \rangle \langle \Psi_n | \gamma_{n'} \rangle - \langle \gamma_{m'} | \Phi_m \rangle \langle \Phi_n | \gamma_{n'} \rangle| \quad (213)$$

$$\leq \sqrt{\sum_{m,m'} \sum_{n,n'} |b_{mm'} b_{nn'}^* c_{m'} c_{n'}|^2} \cdot O(\varepsilon) \quad (214)$$

$$= \sqrt{\sum_{m,m'} |b_{mm'}|^2 c_{m'}^2} \sqrt{\sum_{n,n'} |b_{nn'}|^2 c_{n'}^2} \cdot O(\varepsilon) \quad (215)$$

$$\leq \sqrt{\sum_{m,m'} |b_{mm'}|^2} \sqrt{\sum_{n,n'} |b_{nn'}|^2} \cdot O(\varepsilon) \quad (216)$$

$$= O(\varepsilon), \quad (217)$$

where (212) comes from (208) and (209), (214) comes from (210) and orthogonality of the states $|\gamma_{m'}\rangle$, and (217) comes from the assumption that $\sum_m \sum_{m'} |b_{mm'}|^2 = 1$. \square

Finally, we use Lemma 5, Lemma 6, and Proposition 3 to prove Lemma 4.

Proof of Lemma 4. Plugging Lemma 6 into Proposition 3 by taking $V = V_\epsilon$, $\varepsilon = k^4 \epsilon^2$, and $d = 2$, we know that

$$\|\mathcal{E}_\epsilon - \mathcal{E}'_\epsilon\|_\diamond = O(k^4 \epsilon^2), \quad (218)$$

where $\mathcal{E}_\epsilon(\rho) := \text{Tr}_{\text{anc}}[e^{-iH\frac{\pi}{2}}(|2\rangle\langle 2| \otimes \rho)e^{iH\frac{\pi}{2}}]$. Together with Lemma 5, we have shown that the quantum operation \mathcal{E}_ϵ satisfies Lemma 4. Furthermore, H is a $(k^2 + 1)$ -sparse Hamiltonian, so by Theorem 1 of [10], \mathcal{E}_ϵ can be implemented using $O(k^2[\log N + \log^{5/2}(k/\epsilon)] \frac{\log(k/\epsilon)}{\log \log(k/\epsilon)})$ 2-qubit gates and $O(k^2 \frac{\log(k/\epsilon)}{\log \log(k/\epsilon)})$ queries to the black box. \square

5.3 Truncated damped quantum harmonic oscillators

In this section we briefly describe an application of the above simulation, namely to simulating a damped quantum harmonic oscillator truncated to the first N levels in Fock space. This system is described by the creation operator a^\dagger and its Hermitian conjugate, the annihilation operator a , satisfying

$$a^\dagger |j\rangle = \sqrt{j+1} |j+1\rangle \quad a |j\rangle = \sqrt{j} |j-1\rangle, \quad (219)$$

where $|n\rangle = 0$ if $n > N - 1$. Then the Lindbladians

$$\mathcal{L}_{\text{up}}(\rho) := \frac{1}{N} (a^\dagger \rho a - \frac{1}{2} (a a^\dagger \rho + \rho a a^\dagger)) \quad (220)$$

$$\mathcal{L}_{\text{down}}(\rho) := \frac{1}{N} (a \rho a^\dagger - \frac{1}{2} (a^\dagger a \rho + \rho a^\dagger a)) \quad (221)$$

are not local, but they can be efficiently simulated by Theorem 8:

Corollary 1. *For any time $t > 0$, the Lindbladians \mathcal{L}_{up} and $\mathcal{L}_{\text{down}}$ can both be simulated within error ϵ using $O(\frac{t^2 \log N}{\epsilon})$ 2-qubit gates.*

The Lindbladian $\mathcal{L}_{\text{down}}$ represents damping at zero temperature, whereas \mathcal{L}_{up} represents damping at infinite temperature. More generally, Lindbladians of the form $\lambda \mathcal{L}_{\text{up}} + (1 - \lambda) \mathcal{L}_{\text{down}}$ for $0 < \lambda < 1$ represent generalized damping at finite temperature, and can also be simulated efficiently.

6 Open quantum walks

This section briefly discusses possible applications of our simulation methods to implementations of non-unitary quantum walks.

6.1 Quantum stochastic walks

Reference [45] introduced the notion of quantum stochastic walks, a mutual generalization of classical random walks and quantum walks. Specifically, given a graph $G = (V, E)$ and a continuous-time classical Markov chain on G with transition rate matrix M , consider Lindblad operators $L_{k,l} = \sqrt{M_{k,l}}|k\rangle\langle l|$ for each $k \neq l$. This gives a diagonal Lindbladian \mathcal{L} of the form of equation (75), where for each m we have

$$\mathcal{L}(|m\rangle\langle m|) = \sum_{k \neq m} M_{k,m}(|k\rangle\langle k| - |m\rangle\langle m|). \quad (222)$$

In other words, \mathcal{L} simulates the classical Markov chain on diagonal states. On the other hand, a continuous-time quantum walk is characterized by a Hamiltonian $\mathcal{H}(\rho) := -i[H, \rho]$, which can appear as part of a Lindbladian as in (1) and (2). By taking a positive linear combination of \mathcal{H} and \mathcal{L} , we obtain a quantum stochastic walk, generalizing classical random walks and quantum walks.

If the underlying graph G of the Lindbladian \mathcal{L} in (222) is sparse, then \mathcal{L} is a sparse-diagonal Lindbladian and it can be efficiently simulated by Theorem 5. This shows that quantum stochastic walks on sparse graphs can be carried out in practice. To the best of our knowledge, this was not known previously.

As a concrete example, consider the unweighted random walk on G defined by

$$M_{k,l} = \begin{cases} \frac{1}{\deg(l)} & \text{if } (k,l) \in E \\ 0 & \text{if } (k,l) \notin E. \end{cases} \quad (223)$$

We can use quantum stochastic walks to prepare the stationary state of such a process:

Theorem 9 ([30]). *If G is connected, then for any Hamiltonian \mathcal{H} , the Lindbladian $\mathcal{H} + \mathcal{L}$ is relaxing, i.e., there exists a unique stationary state ρ_∞ such that $e^{\mathcal{L}t}(\rho_\infty) = \rho_\infty$ for any time t and $\lim_{t \rightarrow \infty} e^{\mathcal{L}t}(\rho) = \rho_\infty$ for any initial state ρ . Furthermore, if G is both connected and regular, then $\rho_\infty = \frac{1}{|V|}I$.*

If G is connected but not regular, then the state ρ_∞ in Theorem 9 can be complicated even though G is not. For instance, if $V = \{v_1, v_2, v_3\}$, $E = \{(v_1, v_2), (v_2, v_3)\}$, and the Hamiltonian H is the Laplacian of G , then [30] showed that

$$\rho_\infty = \begin{pmatrix} \frac{2}{7} & -\frac{1}{28} + \frac{1}{28}i & -\frac{1}{14} \\ -\frac{1}{28} - \frac{1}{28}i & \frac{3}{7} & -\frac{1}{28} - \frac{1}{28}i \\ \frac{1}{14} & -\frac{1}{28} + \frac{1}{28}i & \frac{2}{7} \end{pmatrix}. \quad (224)$$

This type of behavior may be of interest for quantum state engineering or dissipative quantum computation [28, 42].

6.2 Decoherence in quantum walks on the hypercube

There is an extensive literature on the effects of decoherence on quantum walks. In particular, references [2, 35] discussed models of decoherence in quantum walks on the hypercube, the graph with vertex set $V = \{0, 1\}^n$ and edge set $E = \{(x, y) \in V^2 : \Delta(x, y) = 1\}$, where $\Delta(x, y)$ denotes the Hamming distance between the strings x and y . The adjacency matrix of the hypercube is

$$A = \sum_{j=1}^n \sigma_x^{(j)} \quad (225)$$

where $\sigma_x^{(j)}$ denotes the Pauli X operator acting on the j th qubit.

For simplicity, we consider the quantum walk with the Hamiltonian given by A instead of the Laplacian, because the hypercube is a regular graph and the walks generated by the adjacency matrix and the Laplacian only differ by a global phase.

Reference [2] considered the decoherence model with Lindblad operators

$$L_{j,\alpha} := I \otimes \cdots \otimes I \otimes \Pi_\alpha \otimes I \otimes \cdots \otimes I, \quad (226)$$

where $\alpha \in \{0, 1\}$, $j \in \{1, 2, \dots, n\}$, and $\Pi_\alpha := |\alpha\rangle\langle\alpha|$ acts on the j th qubit. The Lindbladian is

$$\mathcal{L}(\rho) := -(1-p)i[A, \rho] + p \sum_{j,\alpha} (L_{j,\alpha} \rho L_{j,\alpha}^\dagger - \frac{1}{2} L_{j,\alpha}^\dagger L_{j,\alpha} \rho - \frac{1}{2} \rho L_{j,\alpha}^\dagger L_{j,\alpha}), \quad (227)$$

where $0 < p < 4/n$ is the probability of decoherence per unit time. This \mathcal{L} can be efficiently simulated using Theorem 3 and the fact that efficient simulation is closed under positive linear combinations.

Reference [35] considered another decoherence model with Lindblad operators

$$L_x := \Pi_{x_1} \otimes \cdots \otimes \Pi_{x_n}, \quad (228)$$

where $x \in \{0, 1\}^n$. The Lindbladian is

$$\mathcal{L}(\rho) := -i[A, \rho] + \lambda \sum_x (L_x \rho L_x^\dagger - \frac{1}{2} L_x^\dagger L_x \rho - \frac{1}{2} \rho L_x^\dagger L_x), \quad (229)$$

where $\lambda \ll 1$. The matrix A in (3) of this \mathcal{L} satisfies $A_{(x,x),(x,x)} = \frac{1}{2}\lambda$ for all $x \in \{0, 1\}^n$ and $A_{(k,l),(k',l')} = 0$ otherwise. By taking $a_x = \frac{1}{2}\lambda$ and $c_x = 0$ for all x in Theorem 4, we see that this is an identical-coordinate Lindbladian, so it can be efficiently simulated.

References [2, 35] studied the hitting and mixing times of these walks, showing that they can sometimes achieve the fast hitting time of a quantum walk while also retaining fast convergence to a uniform distribution as in a classical random walk. Our work shows that this process can be implemented efficiently, and we hope this may lead to practical applications of open quantum walks.

7 Linear limit on simulation time

Reference [6] established a so-called no-fast-forwarding theorem for Hamiltonian simulation, showing that simulating a Hamiltonian H for time t with constant precision requires $\Omega(t)$ queries to a black box description of H . This result shows that one cannot fast-forward the dynamics of a generic Hamiltonian. Here we extend this result to Lindbladians in two different query models.

Theorem 10 (No-fast-forwarding theorem for Lindbladians). *For any positive integer $N \geq 7$, there exists a Lindbladian \mathcal{L} generated by a single Lindblad operator L such that $\|\mathcal{L}\|_\diamond = 1$ and simulating the evolution of \mathcal{L} for time $t = 4N$ within precision $1/8$ requires at least*

- (i) $N/4 = t/16$ queries to a black box that takes both a row and column index of the matrix A of \mathcal{L} defined in (3) and outputs the corresponding entry in A , or
- (ii) $N/2 = t/8$ queries to a black box that takes a row or column index of L as input and outputs the locations and values of all nonzero elements in that row or column.

To prove Theorem 10, we first establish two lemmas:

Lemma 7. *For all positive integers $N \geq 7$,*

$$\sum_{m=0}^{N-1} \frac{(2N)^m e^{-2N}}{m!} \leq \frac{1}{64}. \quad (230)$$

Proof. When $N = 7, 8, 9, 10, 11, 12$, (230) holds. It suffices to prove (230) when $N \geq 13$.

A theorem of Ramanujan [23, Question 294] states that for any positive integer M ,

$$\frac{1}{2}e^M = \sum_{m=0}^{M-1} \frac{M^m}{m!} + \theta(M) \cdot \frac{M^M}{M!}, \quad (231)$$

where $\frac{1}{3} \leq \theta(M) \leq \frac{1}{2} \forall M$. Therefore,

$$\frac{1}{2}e^{2N} \geq \sum_{m=0}^{2N-1} \frac{(2N)^m}{m!}. \quad (232)$$

If

$$\sum_{m=N}^{2N-1} \frac{(2N)^m}{m!} \geq 31 \cdot \sum_{m=0}^{N-1} \frac{(2N)^m}{m!}, \quad (233)$$

then (232) gives

$$\frac{1}{2}e^{2N} \geq \sum_{m=0}^{N-1} \frac{(2N)^m}{m!} + 31 \cdot \sum_{m=0}^{N-1} \frac{(2N)^m}{m!} \Rightarrow \sum_{m=0}^{N-1} \frac{(2N)^m e^{-2N}}{m!} \leq \frac{1}{64}. \quad (234)$$

Hence it suffices to prove (233), which holds provided

$$\frac{(2N)^{m+N}}{(m+N)!} \geq 31 \cdot \frac{(2N)^m}{m!} \quad \forall m \in [N]. \quad (235)$$

Moreover, since

$$\frac{\frac{(2N)^{m+1+N}}{(m+1+N)!} / \frac{(2N)^{m+1}}{(m+1)!}}{\frac{(2N)^{m+N}}{(m+N)!} / \frac{(2N)^m}{m!}} = \frac{m+1}{m+1+N} < 1 \quad \forall m \in [N], \quad (236)$$

it suffices to prove

$$\frac{(2N)^{2N}}{(2N)!} \geq 31 \cdot \frac{(2N)^N}{N!}. \quad (237)$$

Define $g(N) := \frac{(2N)^{2N}}{(2N)!} / \frac{(2N)^N}{N!}$. Since $g(13) \approx 38.3102 > 31$ and

$$\frac{g(N+1)}{g(N)} = \frac{N+1}{2N+1} \cdot \left(1 + \frac{1}{N}\right)^N > \frac{1}{2} \cdot 2 = 1 \quad \forall N, \quad (238)$$

we have $g(N) > 31$ for $N \geq 13$. Therefore, (237) holds and (230) follows. \square

Lemma 8. Consider the Lindblad operator L acting in \mathbb{C}^{N+1} such that

$$L|0\rangle = 0, \quad L|n\rangle = |n-1\rangle \quad \forall n \in \{1, \dots, N\}. \quad (239)$$

Then for any time $t > 0$, the Lindbladian $\mathcal{L}(\rho) := L\rho L^\dagger - \frac{1}{2}(L^\dagger L\rho + \rho L^\dagger L)$ satisfies

$$e^{\mathcal{L}t}(|N\rangle\langle N|) = \sum_{m=0}^{N-1} \frac{t^m e^{-t}}{m!} |N-m\rangle\langle N-m| + \left(1 - \sum_{m=0}^{N-1} \frac{t^m e^{-t}}{m!}\right) |0\rangle\langle 0|. \quad (240)$$

Proof. We have

$$\mathcal{L}(|n\rangle\langle n|) = |n-1\rangle\langle n-1| - |n\rangle\langle n| \quad \forall n \in \{1, 2, \dots, N\}; \quad (241)$$

$$\mathcal{L}(|0\rangle\langle 0|) = 0. \quad (242)$$

Denote $C := (|N\rangle\langle N|, |N-1\rangle\langle N-1|, \dots, |0\rangle\langle 0|)^\dagger$, and let A be the $(N+1) \times (N+1)$ matrix with nonzero entries $A_{n,n} = -1$ and $A_{n,n+1} = 1 \quad \forall n \in [N]$. In other words,

$$A = \begin{pmatrix} -1 & 1 & & & \\ & \ddots & \ddots & & \\ & & -1 & 1 & \\ & & & & 0 \end{pmatrix}. \quad (243)$$

Then $\mathcal{L}(C) = AC$, so

$$e^{\mathcal{L}t}(C) = e^{tA}C. \quad (244)$$

Since every row of A has zero sum, $\mathbf{e} = (1, 1, \dots, 1)^\dagger$ satisfies $A\mathbf{e} = 0$. Therefore, $e^{tA}\mathbf{e} = \mathbf{e}$, so

$$(e^{tA})_{0,N} = 1 - \sum_{m=0}^{N-1} (e^{tA})_{0,m}. \quad (245)$$

By induction, for arbitrary $n \in \mathbb{N}$ we have

$$(A^n)_{0,m} = \binom{n}{m} (-1)^{n+m} \quad \forall m \in [N]. \quad (246)$$

Therefore,

$$(e^{tA})_{0,m} = \sum_{n=0}^{\infty} \frac{(A^n)_{0,m} t^n}{n!} = \sum_{n=0}^{\infty} \frac{\binom{n}{m} (-1)^{n+m} t^n}{n!} = \frac{t^m}{m!} \sum_{n=m}^{\infty} \frac{(-1)^{n-m} t^{n-m}}{(n-m)!} = \frac{t^m e^{-t}}{m!}. \quad (247)$$

Combining (245) and (247), we get

$$(e^{tA})_{0,N} = 1 - \sum_{m=0}^{N-1} \frac{t^m e^{-t}}{m!}. \quad (248)$$

Finally, (240) follows from (247) and (248). \square

Proof of Theorem 10. We now construct a Lindbladian whose dynamics compute the parity of a string $s \in \{0, 1\}^N$, analogous to the Hamiltonian constructed in [6]. Specifically, let

$$\mathcal{L}_s(\rho) = \frac{1}{2}(L_s \rho L_s^\dagger - \frac{1}{2}(L_s^\dagger L_s \rho + \rho L_s^\dagger L_s)) \quad (249)$$

be a Lindbladian acting on the $2(N+1)$ -dimensional Hilbert space $\mathcal{H} \otimes \mathbb{C}^2$, where $s = s_1 s_2 \cdots s_N$ is a binary string and

$$L_s|0, j\rangle = 0, \quad L_s|n, j\rangle = |n-1, j \oplus s_n\rangle \quad \forall n \in \{1, 2, \dots, N\}, j \in \{0, 1\}. \quad (250)$$

First we prove $\|\mathcal{L}_s\|_\diamond = 1$. Let \mathcal{I}_m denote the identity superoperator on \mathbb{C}^m . Since $2\mathcal{L}_s$ is a permutation of $\mathcal{L} \otimes \mathcal{I}_2$ where \mathcal{L} is the Lindbladian in Lemma 8,

$$2\|\mathcal{L}_s\|_\diamond = \|\mathcal{L} \otimes \mathcal{I}_2\|_\diamond = \|\mathcal{L} \otimes \mathcal{I}_2 \otimes \mathcal{I}_{2(N+1)}\|_{1 \rightarrow 1} = \|\mathcal{L} \otimes \mathcal{I}_{4(N+1)}\|_{1 \rightarrow 1} = \|\mathcal{L} \otimes \mathcal{I}_{N+1}\|_{1 \rightarrow 1} \quad (251)$$

where the $\|\cdot\|_{1 \rightarrow 1}$ norm is defined in (29) and the last equality comes from the fact that $\|\mathcal{L} \otimes \mathcal{I}_m\|_{1 \rightarrow 1} = \|\mathcal{L} \otimes \mathcal{I}_{N+1}\|_{1 \rightarrow 1}$ for any $m \geq N+1$ (see Section 3.3 of [44]). Thus it suffices to show that

$$\|\mathcal{L} \otimes \mathcal{I}_{N+1}\|_{1 \rightarrow 1} = 2. \quad (252)$$

On the one hand, $\|\mathcal{L}(|N\rangle\langle N|)\|_1 = \| |N-1\rangle\langle N-1| - |N\rangle\langle N| \|_1 = 2$, so

$$\|\mathcal{L} \otimes \mathcal{I}_{N+1}\|_{1 \rightarrow 1} \geq \|\mathcal{L}\|_{1 \rightarrow 1} \geq 2. \quad (253)$$

On the other hand, for any pure state $|\Phi\rangle = \sum_{m,m'=0}^N b_{mm'}|m\rangle|m'\rangle$,

$$\|(L \otimes I_{N+1})|\Phi\rangle\langle\Phi|(L^\dagger \otimes I_{N+1})\|_1 = \left\| \sum_{m,n=1}^N \sum_{m',n'=0}^N b_{mm'} b_{nn'}^* |m-1\rangle\langle n-1| \otimes |m'\rangle\langle n'| \right\|_1 \quad (254)$$

$$= \left\| \sum_{m=1}^N \sum_{m'=0}^N b_{mm'} |m-1\rangle\langle m'| \right\|^2 \quad (255)$$

$$= \sum_{m=1}^N \sum_{m'=0}^N |b_{mm'}|^2 \quad (256)$$

$$\leq \sum_{m=0}^N \sum_{m'=0}^N |b_{mm'}|^2 \quad (257)$$

$$= 1. \quad (258)$$

Similarly,

$$\|(L^\dagger \otimes I_{N+1})(L \otimes I_{N+1})|\Phi\rangle\langle\Phi|\|_1, \|\Phi\rangle\langle\Phi|(L^\dagger \otimes I_{N+1})(L \otimes I_{N+1})\|_1 \leq 1. \quad (259)$$

Therefore, for any density matrix $\rho \in \mathcal{L}(\mathbb{C}^{N+1} \otimes \mathbb{C}^{N+1})$, by subadditivity of the trace norm

$$\|\mathcal{L} \otimes \mathcal{I}_{N+1}(\rho)\|_1 \leq 1 + \frac{1}{2}(1+1) = 2 \quad \Rightarrow \quad \|\mathcal{L} \otimes \mathcal{I}_{N+1}\|_{1 \rightarrow 1} \leq 2. \quad (260)$$

Clearly (252) follows from (253) and (260). Therefore, we have shown $\|\mathcal{L}_s\|_\diamond = 1$.

To complete the proof, we show how a simulation can be used to compute the parity of s . Let $\text{PARITY}(s) := s_1 \oplus s_2 \oplus \cdots \oplus s_N$. We simulate \mathcal{L}_s with initial state $|N, 0\rangle\langle N, 0|$, and after

time $t = 4N$ we measure the system. By [Lemma 7](#), [Lemma 8](#), and [\(249\)](#), the probability that the measurement result is not $(0, \text{PARITY}(s))$ is

$$p \leq \frac{1}{64}. \quad (261)$$

In the simulation of \mathcal{L}_s , denote the final state of the ancilla by ρ_{anc} . Let

$$\rho_s := |\text{PARITY}(s)\rangle\langle\text{PARITY}(s)|, \quad (262)$$

$$\rho_{s,\text{sim}} := \text{Tr}_{\mathcal{H}}[e^{\mathcal{L}_s t}(|N, 0\rangle\langle N, 0|)]. \quad (263)$$

By the definition of p , we have

$$\langle\text{PARITY}(s)|\rho_{s,\text{sim}}|\text{PARITY}(s)\rangle \geq 1 - p. \quad (264)$$

By [\[5\]](#) and [\[19\]](#), the parity of N bits requires $\frac{N}{2}$ bits of s to compute within error $\frac{1}{4}$. Therefore, if we only learn fewer than $\frac{N}{2}$ bits of s ,

$$D(\rho_{\text{anc}}, \rho_s) \geq \frac{1}{4}, \quad (265)$$

where $D(\rho, \sigma) := \frac{1}{2}\|\rho - \sigma\|_1$ is the trace distance.

On the other hand, we claim that the simulation accurately produces ρ_s . To see this, let $q := \langle 1 - \text{PARITY}(s) | \rho_{s,\text{sim}} | 1 - \text{PARITY}(s) \rangle$ and $r := \langle \text{PARITY}(s) | \rho_{s,\text{sim}} | 1 - \text{PARITY}(s) \rangle$. By [\(264\)](#), $q \leq p$. Write $\rho_{s,\text{sim}}$ in the basis $\{|\text{PARITY}(s)\rangle, |1 - \text{PARITY}(s)\rangle\}$:

$$\rho_{s,\text{sim}} = \begin{pmatrix} 1 - q & r \\ r^* & q \end{pmatrix}. \quad (266)$$

Since $\rho_{s,\text{sim}} \geq 0$, we have $|r|^2 \leq q(1 - q)$. Consequently,

$$D(\rho_s, \rho_{s,\text{sim}}) = \left\| \begin{pmatrix} -q & r \\ r^* & q \end{pmatrix} \right\|_1 = \sqrt{q^2 + |r|^2} \leq \sqrt{q^2 + q(1 - q)} \leq \sqrt{p} \leq \frac{1}{8}, \quad (267)$$

where the last inequality comes from [\(261\)](#).

Therefore, by [\(265\)](#), [\(267\)](#), and the triangle inequality,

$$D(\rho_{\text{anc}}, \rho_{s,\text{sim}}) \geq D(\rho_{\text{anc}}, \rho_s) - D(\rho_s, \rho_{s,\text{sim}}) \geq \frac{1}{4} - \frac{1}{8} = \frac{1}{8}. \quad (268)$$

A nonzero element of the matrix A_s of \mathcal{L}_s defined in [\(3\)](#) has row coordinate $((n_1 - 1) + (N + 1)(j_1 \oplus s_{n_1}), n_1 + (N + 1)j_1)$ and column coordinate $((n_2 - 1) + (N + 1)(j_2 \oplus s_{n_2}), n_2 + (N + 1)j_2)$ for some $n_1, n_2 \in [N + 1]$ and $j_1, j_2 \in \{0, 1\}$. As a result, using the first query model considered in [Theorem 10](#), one query to the Lindbladian can be simulated using at most two queries to the bits of s (s_{n_1} and s_{n_2}). With the second query model, one query to the Lindbladian can be simulated using a single query to a bit of s because a nonzero element of the Lindblad operator L_s has row coordinate $(n - 1) + (N + 1)(j \oplus s_n)$ and column coordinate $n + (N + 1)j$ for some $n \in [N + 1]$ and $j \in \{0, 1\}$. Therefore, [\(268\)](#) shows that at least $\frac{N}{4} = \frac{t}{16}$ queries to the first black box, or at least $\frac{N}{2} = \frac{t}{8}$ queries to the second black box, are needed to simulate \mathcal{L}_s for time $t = 4N$ within precision $\frac{1}{8}$. \square

8 Conclusion and future work

In this paper, we have developed quantum algorithms for efficiently simulating Lindbladians that are not necessarily local. We introduced two approaches to this problem, one based on implementing sparse Stinespring isometries and another based on implementing short-time evolutions generated by sparse Lindblad operators.

We hope that future work will expand the scope of our algorithms to simulate broader and more unified classes of sparse Lindbladians. We also hope these tools will prove useful for simulating realistic quantum systems and for developing novel quantum algorithms.

A concrete challenge for future work is to efficiently simulate the Davies master equation [17]. For any given Hamiltonian and temperature, the Davies master equation describes a Markovian open system that converges to the Gibbs state of the Hamiltonian at that temperature. While the quantum Metropolis algorithm [40, 46] can be used to prepare this Gibbs state, simulating the Davies equation would provide a method of simulating the approach to equilibrium. Note that the overcomplete GKS matrix for the Davies master equation is diagonal in the eigenbasis of its system Hamiltonian, but it is not obvious how to apply our methods in that basis.

Another natural question is to improve the complexity of simulating open quantum systems as a function of the allowed error, ϵ . The simulations presented in this paper have complexity $\text{poly}(1/\epsilon)$, and it is natural to ask whether there is an algorithm with complexity $\text{poly}(\log 1/\epsilon)$, as in the case of Hamiltonian simulation [8].

Acknowledgments

We thank Richard Cleve for discussions that helped to motivate the simulation method presented in Section 5. We acknowledge support from the Canadian Institute for Advanced Research and the National Science Foundation (grant 1526380).

A Gram matrix decomposition for low-rank cases

In Section 4.1, we described how to simulate local Lindbladians using the sparse Stinespring isometry framework. That simulation relied on an algorithm for computing the Gram vector corresponding to a given basis state, which we describe in detail here.

Lemma 9. *Let M be an $N \times N$ Gram matrix with rank r . Suppose we are given a black box for the entries of M and are told the coordinates of a full-rank principal submatrix. Then Algorithm 1 takes $x \in [N]$ as input and prepares the Gram vector v_x of M as a quantum state using $O(r^3)$ time and $O(r^2)$ queries to the entries of M (in particular, both bounds are independent of N).*

Proof. Algorithm 1 makes at most $(r+1)^2 = O(r^2)$ queries to the entries of M because we only ask for $M_{S \cup \{x\}}$. The matrix diagonalization in line 1 and line 5 takes $O(r^3)$ time, and line 6 can be done in $O(r^3)$ time by computing the inverse matrix of (v'_1, \dots, v'_r) to get $(c_1, \dots, c_r)^\dagger = (v'_1, \dots, v'_r)^{-1} v'_x$, which is equivalent to $\sum_{i=1}^r c_i v'_i = v'_x$; therefore,

$$v_x = U_x v'_x = \sum_{i=1}^r c_i U_x v'_i = \sum_{i=1}^r c_i v_i. \quad (269)$$

Now we show correctness. Without loss of generality, assume $S = \{1, 2, \dots, r\}$. Since M has rank r and M_S is a submatrix of M with full-rank r , all rows in M can be written as a linear

Algorithm 1: Preparing a Gram vector of a low-rank Gram matrix

Input: The rank r of M ; an index $x \in [N]$; $S \subseteq [N]$, where $|S| = r$ and the rows and columns specified by S constitute a full-rank principal submatrix of M .

Output: Quantum state $|v_x\rangle$ proportional to the x th Gram vector of M .

1 Let M_S denote the principal submatrix of the rows and columns in S . Diagonalize it as

$$M_S = UDU^\dagger. \text{ Denote } (v_1, v_2, \dots, v_r)^\dagger := U\sqrt{D}.$$

2 **if** $x \in S$ **then**

3 Let $v := v_x$.

4 **else**

5 Let $M_{S \cup \{x\}}$ be the principal submatrix of the rows and columns in $S \cup \{x\}$. Diagonalize it as $M_{S \cup \{x\}} = U' \text{diag}(d_1, \dots, d_r, 0)U'^\dagger$. Denote

$$(v'_1, v'_2, \dots, v'_r, v'_x)^\dagger := U' \begin{pmatrix} \sqrt{d_1} & & & \\ & \ddots & & \\ & & \sqrt{d_r} & \\ & & & 0 \end{pmatrix}.$$

6 Find the unitary U_x such that $U_x v'_i = v_i \ \forall i \in \{1, \dots, r\}$. Let $v := U_x v'_x$.

7 Prepare a quantum state $|v\rangle$ proportional to v using the method of reference [34].

combination of all rows in S . Therefore, if we can show that $v_i^\dagger v_x = M_{ix}$ for arbitrary $i \in \{1, \dots, r\}$ and $x \in \{1, \dots, N\}$, then we have $v_y^\dagger v_x = M_{yx}$ for arbitrary $x, y \in \{1, \dots, N\}$, so we have found the correct Gram vectors.

Since

$$v_i^\dagger v'_x = v_i^\dagger U_x U_x^\dagger v_x = v_i^\dagger v_x, \quad (270)$$

it suffices to show that $v_i^\dagger v'_x = M_{ix}$ for arbitrary $i \in \{1, \dots, r\}$ and $x \in \{1, \dots, N\}$. But this is trivial because line 5 of the algorithm promises

$$\begin{aligned} & (v'_1, v'_2, \dots, v'_r, v'_x)^\dagger (v'_1, v'_2, \dots, v'_r, v'_x) \\ &= U' \begin{pmatrix} \sqrt{d_1} & & & \\ & \ddots & & \\ & & \sqrt{d_r} & \\ & & & 0 \end{pmatrix} \begin{pmatrix} \sqrt{d_1} & & & \\ & \ddots & & \\ & & \sqrt{d_r} & 0 \end{pmatrix} U'^\dagger \end{aligned} \quad (271)$$

$$= U' \text{diag}(d_1, \dots, d_r, 0) U'^\dagger \quad (272)$$

$$= M_{S \cup \{x\}}, \quad (273)$$

which gives $v_i^\dagger v'_x = M_{ix}$.

Finally, by reference [34] we can prepare v_x as a quantum state in $O(r)$ additional time, which is dominated by the $O(r^3)$ time of computing v_x . \square

B Decomposition of sparse diagonal Lindbladians

In this appendix we prove [Lemma 3](#), which states that every d -sparse-diagonal Lindbladian can be written as the sum of at most $3d^2$ strongly 1-sparse-diagonal Lindbladians, and that this decom-

position can be found with constant overhead of queries using the black box in [Theorem 5](#).

We may assume that the diagonal elements of the matrix a characterizing the diagonal Lindbladian are all 0 because, as we have shown in [Lemma 2](#), we can efficiently simulate a diagonal Lindbladian with diagonal matrix a , and efficient Lindbladian simulation is closed under positive linear combination by [Proposition 2](#).

First we show a decomposition without demanding strong sparsity, as follows.

Lemma 10. *Every d -sparse-diagonal Lindbladian can be written as the sum of at most d^2 1-sparse-diagonal Lindbladians with constant overhead in queries using the black box in [Theorem 5](#).*

Proof. We cast the problem in terms of a directed graph $G = (V, E)$ where $V = \{v_1, v_2, \dots, v_N\}$. If $a_{ij} \neq 0$ in the a matrix, then there is a directed edge in E that goes from v_i to v_j . Since a is d -sparse, each vertex in V has in-degree and out-degree at most d . Our aim is to color the edges of the graph with at most d^2 colors such that in the subgraph including only the edges of any given color, each vertex has in-degree and out-degree at most 1 in that subgraph (that is, the subgraph of any given color corresponds to a 1-sparse a).

Let (u, v) denote the directed edge from vertex u to vertex v . For each $i \in \{1, \dots, N\}$, let $\text{num}(v_i) := i$. Define

$$\text{Next}(u) := \{v : (u, v) \in E\}, \quad (274)$$

$$\text{Prev}(v) := \{u : (u, v) \in E\}. \quad (275)$$

If $v \in \text{Next}(u)$, define

$$\text{NextIdx}(u, v) := |\{i : i < \text{num}(v), v_i \in \text{Next}(u)\}|; \quad (276)$$

if $u \in \text{Prev}(v)$, define

$$\text{PrevIdx}(u, v) := |\{i : i < \text{num}(u), u_i \in \text{Prev}(v)\}|. \quad (277)$$

For each pair of $(u, v) \in E$, since $\text{num}(v)$ is excluded in $\text{NextIdx}(u, v)$ and $\text{num}(u)$ is excluded in $\text{PrevIdx}(u, v)$, we have

$$0 \leq \text{NextIdx}(u, v), \text{PrevIdx}(u, v) \leq d - 1. \quad (278)$$

Then we assign the edge (u, v) the color $d \cdot \text{NextIdx}(u, v) + \text{PrevIdx}(u, v)$.

We claim that for the edges in the subgraph of any given color, each vertex has in-degree at most 1. If not, say (u, v) and (u', v) are edges in the same subgraph where $u \neq u'$. This gives $d \cdot \text{NextIdx}(u, v) + \text{PrevIdx}(u, v) = d \cdot \text{NextIdx}(u', v) + \text{PrevIdx}(u', v)$, which by (278) leads to $\text{NextIdx}(u, v) = \text{NextIdx}(u', v)$ and $\text{PrevIdx}(u, v) = \text{PrevIdx}(u', v)$. From the latter, we get $u = u'$, a contradiction. By an analogous argument, the out-degree of each vertex in a given subgraph is at most 1. Therefore, each subgraph corresponds to a 1-sparse-diagonal Lindbladian. By (278), we get at most d^2 subgraphs.

For each edge $(u, v) \in E$, the coloring only needs to ask the black box stated in [Theorem 5](#) about the neighbors of u and v , so the decomposition only costs constant overhead in queries to the black box. The resulting black box for each 1-sparse-diagonal Lindbladian takes a color and a vertex as input and outputs the edge with the color that is adjacent to the vertex. \square

It remains to decompose each 1-sparse-diagonal term into strongly 1-sparse-diagonal pieces.

Lemma 11. *Every 1-sparse-diagonal Lindbladian can be written as the sum of at most 3 strongly 1-sparse-diagonal Lindbladians with constant overhead in queries using the black box of the 1-sparse-diagonal Lindbladian stated in [Lemma 10](#).*

Proof. Again consider a directed graph $G = (V, E)$ where $V = \{v_1, v_2, \dots, v_N\}$ and E contains a directed edge from v_i to v_j if $a_{ij} \neq 0$. Since a is 1-sparse, each vertex in V has in-degree and out-degree at most 1. Our aim is to 3-color the edges such that for the subgraph of any given color, each component is either an isolated vertex, a directed edge, or a directed cycle of length 2 (that is, each subgraph corresponds to a strongly 1-sparse a).

Observe that any component of G must be a directed path, a directed cycle, or an isolated vertex. For directed paths, we can color the edges with two alternating colors. For directed cycles with length 2, we can assign both edges the same color. For directed cycles with even length at least 4, we can color the edges with alternating colors. For directed cycles with odd length at least 3, we can color the edges with alternating colors, except that the final edge must be assigned a third color.

These assignments can be made using only three colors, and each resulting subgraph corresponds to a strongly 1-sparse-diagonal Lindbladian.

For each edge $(u, v) \in E$, the coloring only needs to ask the black box stated in [Lemma 10](#) about the neighbors of u and v , so the decomposition only incurs constant overhead in queries to the black box, and it produces a black box for each resulting strongly 1-sparse-diagonal Lindbladian as stated in [Lemma 2](#). \square

[Lemma 3](#) follows by directly combining [Lemma 10](#) and [Lemma 11](#).

C Proofs of lemmas from [Section 5.2](#)

C.1 Proof of [Lemma 5](#)

Proof. Since $L|j\rangle = \sum_{i=1}^k c_{j,i} |\nu_i(j)\rangle$ for all $j \in [N]$,

$$L = \sum_{j=0}^{N-1} \sum_{i=1}^k c_{j,i} |\nu_i(j)\rangle \langle j|; \quad L^\dagger = \sum_{j=0}^{N-1} \sum_{i=1}^k c_{j,i}^* |j\rangle \langle \nu_i(j)|. \quad (279)$$

Thus for any $m, n \in [N]$,

$$\begin{aligned} (1 + \epsilon \mathcal{L})(|m\rangle \langle n|) &= -\frac{\epsilon}{2} \sum_{i,j=1}^k (c_{m,i} c_{\nu_j^{-1}(\nu_i(m)),j}^* |\nu_j^{-1}(\nu_i(m))\rangle \langle n| + c_{n,i}^* c_{\nu_j^{-1}(\nu_i(n)),j} |m\rangle \langle \nu_j^{-1}(\nu_i(n))|) \\ &\quad + \epsilon \sum_{i,j=1}^k c_{m,i} c_{n,j}^* |\nu_i(m)\rangle \langle \nu_j(n)| + |m\rangle \langle n|. \end{aligned} \quad (280)$$

On the other hand,

$$\begin{aligned}
\text{Tr}_{\text{anc}}[V_\epsilon|m\rangle\langle n|V_\epsilon^\dagger] &= \frac{\epsilon^2}{4} \sum_{1 \leq i \neq j \leq k, 1 \leq i' \neq j' \leq k} c_{m,i} c_{\nu_j^{-1}(\nu_i(m)),j}^* c_{n,i'} c_{\nu_{j'}^{-1}(\nu_{i'}(n)),j'}^* |\nu_j^{-1}(\nu_i(m))\rangle \langle \nu_{j'}^{-1}(\nu_{i'}(n))| \\
&\quad - \epsilon \sum_{1 \leq i \neq j \leq k} \frac{1}{2} c_{m,i} c_{\nu_j^{-1}(\nu_i(m)),j}^* |\nu_j^{-1}(\nu_i(m))\rangle \langle n| \\
&\quad - \epsilon \sum_{1 \leq i \neq j \leq k} \frac{1}{2} c_{n,i} c_{\nu_j^{-1}(\nu_i(n)),j}^* |m\rangle \langle \nu_j^{-1}(\nu_i(n))| \\
&\quad + \epsilon \sum_{i,j=1}^k c_{m,i} c_{n,j}^* |\nu_i(m)\rangle \langle \nu_j(n)| + |m\rangle \langle n|. \tag{281}
\end{aligned}$$

Taking the difference between the above equality and (280), we have

$$\begin{aligned}
(1 + \epsilon \mathcal{L})(|m\rangle\langle n|) - \text{Tr}_{\text{anc}}[V_\epsilon|m\rangle\langle n|V_\epsilon^\dagger] \\
= -\frac{\epsilon^2}{4} \sum_{1 \leq i \neq j \leq k, 1 \leq i' \neq j' \leq k} c_{m,i} c_{\nu_j^{-1}(\nu_i(m)),j}^* c_{n,i'} c_{\nu_{j'}^{-1}(\nu_{i'}(n)),j'}^* |\nu_j^{-1}(\nu_i(m))\rangle \langle \nu_{j'}^{-1}(\nu_{i'}(n))|. \tag{282}
\end{aligned}$$

By subadditivity of the trace norm, it suffices to show that for any pure state

$$|\Phi\rangle = \sum_{m,m'=0}^{N-1} b_{mm'} |m\rangle |m'\rangle \tag{283}$$

with $\sum_{m,m'=0}^{N-1} |b_{mm'}|^2 = 1$, we have

$$\|((1 + \epsilon \mathcal{L}) \otimes \mathcal{I}_N)(|\Phi\rangle\langle\Phi|) - \text{Tr}_{\text{anc}}[(V_\epsilon \otimes I_N)|\Phi\rangle\langle\Phi|(V_\epsilon^\dagger \otimes I_N)]\|_1 = O(k^4 \epsilon^2). \tag{284}$$

Indeed,

$$\begin{aligned}
&\left\| \sum_{m,m',n,n'} b_{mm'} b_{nn'}^* \sum_{i \neq j, i' \neq j'} c_{m,i} c_{\nu_j^{-1}(\nu_i(m)),j}^* c_{n,i'} c_{\nu_{j'}^{-1}(\nu_{i'}(n)),j'}^* |\nu_j^{-1}(\nu_i(m))\rangle \langle \nu_{j'}^{-1}(\nu_{i'}(n))| \otimes |m'\rangle \langle n'| \right\|_1 \\
&\leq \sum_{i \neq j, i' \neq j'} \left(\left\| \sum_{m,m'} b_{mm'} c_{m,i} c_{\nu_j^{-1}(\nu_i(m)),j}^* |\nu_j^{-1}(\nu_i(m))\rangle |m'\rangle \right\| \right. \\
&\quad \cdot \left. \left\| \sum_{n,n'} b_{nn'}^* c_{n,i'} c_{\nu_{j'}^{-1}(\nu_{i'}(n)),j'}^* \langle \nu_{j'}^{-1}(\nu_{i'}(n))| \langle n'| \right\| \right) \tag{285}
\end{aligned}$$

$$= \sum_{i \neq j, i' \neq j'} \sqrt{\sum_{m,m'} |b_{mm'}|^2 |c_{m,i}|^2 |c_{\nu_j^{-1}(\nu_i(m)),j}|^2} \sqrt{\sum_{n,n'} |b_{nn'}|^2 |c_{n,i'}|^2 |c_{\nu_{j'}^{-1}(\nu_{i'}(n)),j'}|^2} \tag{286}$$

$$\leq \sum_{i \neq j, i' \neq j'} \sqrt{\sum_{m,m'} |b_{mm'}|^2 \|L\|_{\max}^4} \sqrt{\sum_{n,n'} |b_{nn'}|^2 \|L\|_{\max}^4} \tag{287}$$

$$= k^2(k-1)^2, \tag{288}$$

and by (282) this implies (284). \square

C.2 Proof of Lemma 6

Proof. We have

$$\begin{aligned}
V_\epsilon^\dagger V_\epsilon &= \sum_{m,n} |n\rangle\langle m| \left(\sum_{i=1}^k \sqrt{\epsilon} c_{n,i}^* \langle \nu_i(n) | \langle 1| + \langle n | \langle 0| - \epsilon \sum_{i_1 \neq i_2} \frac{1}{2} c_{n,i_1}^* \cdot c_{\nu_{i_2}^{-1}(\nu_{i_1}(n)), i_2} \langle \nu_{i_2}^{-1}(\nu_{i_1}(n)) | \langle 0| \right) \\
&\quad \cdot \left(\sum_{j=1}^k \sqrt{\epsilon} c_{m,j} |\nu_j(m)\rangle |1\rangle + |m\rangle |0\rangle - \epsilon \sum_{j_1 \neq j_2} \frac{1}{2} c_{m,j_1} \cdot c_{\nu_{j_2}^{-1}(\nu_{j_1}(m)), i_2} |\nu_{j_2}^{-1}(\nu_{j_1}(m))\rangle |0\rangle \right) \quad (289) \\
&= \sum_{m,n} |n\rangle\langle m| \left(\frac{\epsilon^2}{4} \sum_{\nu_{i_2}^{-1}(\nu_{i_1}(n)) = \nu_{j_2}^{-1}(\nu_{j_1}(m))} c_{n,i_1}^* c_{\nu_{i_2}^{-1}(\nu_{i_1}(n)), i_2} c_{m,j_1} c_{\nu_{j_2}^{-1}(\nu_{j_1}(m)), j_2} \right. \\
&\quad - \frac{\epsilon}{2} \sum_{\nu_{j_2}^{-1}(\nu_{j_1}(m)) = n} c_{m,j_1} c_{\nu_{j_2}^{-1}(\nu_{j_1}(m)), j_2} - \frac{\epsilon}{2} \sum_{\nu_{i_2}^{-1}(\nu_{i_1}(n)) = m} c_{n,i_1}^* c_{\nu_{i_2}^{-1}(\nu_{i_1}(n)), i_2} \\
&\quad \left. + \epsilon \sum_{\nu_i(n) = \nu_j(m)} c_{n,i}^* c_{m,j} + \delta_{nm} \right). \quad (290)
\end{aligned}$$

Since

$$\begin{aligned}
&\epsilon \sum_{\nu_i(n) = \nu_j(m)} c_{n,i}^* c_{m,j} - \frac{\epsilon}{2} \sum_{\nu_{j_2}^{-1}(\nu_{j_1}(m)) = n} c_{m,j_1} c_{\nu_{j_2}^{-1}(\nu_{j_1}(m)), j_2} - \frac{\epsilon}{2} \sum_{\nu_{i_2}^{-1}(\nu_{i_1}(n)) = m} c_{n,i_1}^* c_{\nu_{i_2}^{-1}(\nu_{i_1}(n)), i_2} \\
&= \epsilon \sum_{\nu_i(n) = \nu_j(m)} c_{n,i}^* c_{m,j} - \frac{\epsilon}{2} \sum_{\nu_{j_1}(m) = \nu_{j_2}(n)} c_{m,j_1} c_{n,j_2}^* - \frac{\epsilon}{2} \sum_{\nu_{i_1}(n) = \nu_{i_2}(m)} c_{n,i_1}^* c_{m,i_2} \quad (291)
\end{aligned}$$

$$= \epsilon \sum_{\nu_i(n) = \nu_j(m)} c_{n,i}^* c_{m,j} - \frac{\epsilon}{2} \sum_{\nu_i(n) = \nu_j(m)} c_{n,i}^* c_{m,j} - \frac{\epsilon}{2} \sum_{\nu_i(n) = \nu_j(m)} c_{n,i}^* c_{m,j} \quad (292)$$

$$= 0, \quad (293)$$

we know that

$$V_\epsilon^\dagger V_\epsilon - I = \frac{\epsilon^2}{4} \sum_{m,n} |n\rangle\langle m| \sum_{\nu_{i_2}^{-1}(\nu_{i_1}(n)) = \nu_{j_2}^{-1}(\nu_{j_1}(m))} c_{n,i_1}^* c_{\nu_{i_2}^{-1}(\nu_{i_1}(n)), i_2} c_{m,j_1} c_{\nu_{j_2}^{-1}(\nu_{j_1}(m)), j_2}. \quad (294)$$

To prove that $\|V_\epsilon^\dagger V_\epsilon - I\| = O(k^4 \epsilon^2)$, it suffices to show that for any pure state $|\psi\rangle = \sum_{m=0}^{N-1} b_m |m\rangle$ where $\sum_{m=0}^{N-1} |b_m|^2 = 1$,

$$\langle \psi | V_\epsilon^\dagger V_\epsilon - I | \psi \rangle = O(k^4 \epsilon^2). \quad (295)$$

Denote $l := \nu_{i_2}^{-1}(\nu_{i_1}(n)) = \nu_{j_2}^{-1}(\nu_{j_1}(m))$. Then $m = \nu_{j_1}^{-1}(\nu_{j_2}(l))$ and $n = \nu_{i_1}^{-1}(\nu_{i_2}(l))$. Plugging these

into (294), we get

$$\langle \psi | V_\epsilon^\dagger V_\epsilon - I | \psi \rangle = \frac{\epsilon^2}{4} \sum_{l=0}^{N-1} \left| \sum_{i_1, i_2=1}^k b_{\nu_{i_1}^{-1}(\nu_{i_2}(l))} c_{\nu_{i_1}^{-1}(\nu_{i_2}(l)), i_1}^* c_{l, i_2} \right|^2 \quad (296)$$

$$\leq \frac{\epsilon^2}{4} \sum_{l=0}^{N-1} \left(\sum_{i_1, i_2=1}^k |b_{\nu_{i_1}^{-1}(\nu_{i_2}(l))}|^2 \right) \left(\sum_{i_1, i_2=1}^k |c_{\nu_{i_1}^{-1}(\nu_{i_2}(l)), i_1}^* c_{l, i_2}|^2 \right) \quad (297)$$

$$\leq \frac{\epsilon^2}{4} k^2 \|L\|_{\max}^4 \sum_{l=0}^{N-1} \sum_{i_1, i_2=1}^k |b_{\nu_{i_1}^{-1}(\nu_{i_2}(l))}|^2 \quad (298)$$

$$= \frac{\epsilon^2}{4} k^2 \sum_{i_1, i_2=1}^k \sum_{l=0}^{N-1} |b_{\nu_{i_1}^{-1}(\nu_{i_2}(l))}|^2 \quad (299)$$

$$= \frac{k^4 \epsilon^2}{4} \quad (300)$$

$$= O(k^4 \epsilon^2), \quad (301)$$

where the first inequality comes from the Cauchy-Schwartz inequality. \square
